Clinical Trials: NCCN believes that the best management for any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.

Find an NCCN Member Institution:
<https://www.nccn.org/home/member-institutions>.

NCCN Categories of Evidence and Consensus: All recommendations are category 2A unless otherwise indicated.

See [NCCN Categories of Evidence and Consensus](#).

NCCN Categories of Preference: All recommendations are considered appropriate.

See [NCCN Categories of Preference](#).

The NCCN Guidelines for Cervical Cancer include the management of squamous cell carcinoma, adenosquamous carcinoma, adenocarcinoma of the cervix, and small cell neuroendocrine carcinoma of the cervix.

The NCCN Guidelines® are a statement of evidence and consensus of the authors regarding their views of currently accepted approaches to treatment. Any clinician seeking to apply or consult the NCCN Guidelines is expected to use independent medical judgment in the context of individual clinical circumstances to determine any patient's care or treatment. The National Comprehensive Cancer Network® (NCCN®) makes no representations or warranties of any kind regarding their content, use or application and disclaims any responsibility for their application or use in any way. The NCCN Guidelines are copyrighted by National Comprehensive Cancer Network®. All rights reserved. The NCCN Guidelines and the illustrations herein may not be reproduced in any form without the express written permission of NCCN. ©2024.

Updates in Version 3.2024 of the NCCN Guidelines for Cervical Cancer from Version 2.2024 include:

[MS-1](#)

- The Discussion has been updated to reflect the changes in the algorithm.

Updates in Version 2.2024 of the NCCN Guidelines for Cervical Cancer from Version 1.2024 include:

[CERV-6](#)

- Footnote t was revised: Concurrent platinum-containing chemotherapy with EBRT utilizes cisplatin as a single agent (or carboplatin if cisplatin intolerant). *Pembrolizumab may be added with chemoradiation (CRT) **ONLY** for patients with FIGO 2014 Stage III-IVA cervical cancer.* ([See Systemic Therapy for Cervical Cancer \[CERV-F\]](#)). (Also for CERV-7 and CERV-8)

[CERV-F 1 of 3](#) Systemic Therapy for Cervical Cancer

- Chemoradiation; Preferred Regimens: The following footnotes were added to the recommendations for "Cisplatin" and "Carboplatin if patient is cisplatin intolerant"
 - ▶ Footnote c is new: Concurrent platinum-containing chemotherapy with EBRT utilizes cisplatin as a single agent (or carboplatin if cisplatin intolerant). Pembrolizumab may be added with CRT **ONLY** for patients with [FIGO 2014 Stage III-IVA cervical cancer](#). Efficacy of concurrent platinum-containing chemotherapy with EBRT utilizing cisplatin as a single agent with pembrolizumab was evaluated in KEYNOTE-A18 (NCT04221945), a multicenter, randomized, double-blind, placebo-controlled trial with 596 patients with FIGO 2014 Stage III-IVA cervical cancer who had not previously received definitive surgery, radiation, or systemic therapy.
Prescribing information: https://www.accessdata.fda.gov/drugsatfda_docs/label/2024/125514s147lbl.pdf
 - ▶ Footnote d: Checkpoint inhibitors and/or monoclonal antibodies included in this regimen may be continued as maintenance therapy. Refer to the original study protocol for maintenance therapy dosing schedules.

[CERV-F 2 of 3](#)

- Footnote a added: Cisplatin, carboplatin, docetaxel, and paclitaxel may cause drug reactions ([See NCCN Guidelines for Ovarian Cancer--Management of Drug Reactions \[OV-D\]](#)).
- Footnote d added: Checkpoint inhibitors and/or monoclonal antibodies included in this regimen may be continued as maintenance therapy. Refer to the original study protocol for maintenance therapy dosing schedules.
- Footnote removed: Cisplatin or carboplatin, may cause drug reactions. ([See NCCN Guidelines for Ovarian Cancer--Management of Drug Reactions \[OV-D\]](#)).

[CERV-F 3 of 3](#)

- Reference 1 is new: Lorusso D, et al. Pembrolizumab plus chemoradiotherapy for high-risk locally advanced cervical cancer: A randomized double-blind, phase 3 ENGOT-cx11/GOG-3047/KEYNOTE-A18 study. ESMO Congress 2023, LBA38.

Updates in Version 1.2024 of the NCCN Guidelines for Cervical Cancer from Version 1.2023 include:

General

- Terminologies modified to advance the goals of equity, inclusion, and representation.

CERV-2A

- Footnote h revised: "There are no data to support a fertility-sparing approach in small neuroendocrine tumors; *or* gastric type adenocarcinoma; *or* adenoma malignum...."
- Footnote j revised: CKC is the preferred method of diagnostic excision, but LEEP is acceptable, provided adequate margins and proper orientation are obtained. ECC *above the excision* should be added, ~~as clinically indicated~~ *except in pregnancy*. (Also for CERV-3A)

CERV-3

- Stage 1A1 no LVSI; Cone Biopsy; Biopsy Results: The pathways were revised as follows:
 - ▶ Negative margins and *medically* inoperable
 - ▶ Negative margins and *medically* operable
 - ▶ Positive margins for dysplasia or carcinoma *and medically operable*
 - ▶ A new pathway was added for: Positive margins for dysplasia or carcinoma and medically inoperable

CERV-3A

- Footnote m revised: Radiation can be an option for *patients who are* medically inoperable ~~patients or those who refuse surgery~~. (Also for CERV-4)
- Footnote o revised: For *patients who are at* higher risk, ~~patients~~ such as those who are IA2 with LVSI, consideration can be given to adding concurrent platinum-containing chemotherapy with external beam RT (EBRT) utilizing cisplatin as a single agent (or carboplatin if cisplatin intolerant). ([See Systemic Therapy for Cervical Cancer CERV-F](#)).

CERV-4

- Footnote p revised throughout the guidelines: Concurrent platinum-containing chemotherapy with EBRT utilizes cisplatin as a single agent (or carboplatin if cisplatin intolerant). ([See Systemic Therapy for Cervical Cancer CERV-F](#)).
- Footnote q revised: This approach ~~can~~ *should only* be considered in ~~the patients whose extent of disease, response to EBRT, or uterine anatomy precludes adequate coverage by brachytherapy~~ *whose tumor shows a poor response with evidence of residual disease after chemoradiation + image-guided brachytherapy (IGBT) or in patients for whom IGBT is not feasible*.

CERV-7

- Footnote u revised: Consider postoperative imaging (abdomen/pelvis CT *with contrast* or MRI with *and without* contrast) to confirm the adequacy of node removal.

**Updates in Version 1.2024 of the NCCN Guidelines for Cervical Cancer from Version 1.2023 include:****[CERV-9](#)**

- Stage IA2–IB1 cervical carcinoma pathway; Treatment:
 - ▶ Pelvic lymphadenectomy listed as *preferred*.
 - ◊ Recommendation revised: If negative node(s), ~~then observe (preferred)~~
 - ▶ *Pelvic EBRT + brachytherapy ± concurrent platinum-containing chemotherapy (when specimen integrity unknown)* added as an option.
- Footnote n added: [Principles of Radiation Therapy \(CERV-D\)](#).
- Footnote p added: *Concurrent platinum-containing chemotherapy with EBRT utilizes cisplatin as a single agent (or carboplatin if cisplatin intolerant). (See [Systemic Therapy for Cervical Cancer CERV-F](#)).* (Also for CERV-13)

[CERV-10](#)

- Incidental Finding Of Invasive Cancer After Simple (Extracapsular) Hysterectomy; "Optional if Sedlis criteria not met on hysterectomy specimen" pathway: The recommendation "Observe" changed to "Surveillance ([CERV-11](#))".

[CERV-11](#)

- Surveillance; 5th bullet revised: "... exercise, sexual health (eg, vaginal dilator use, lubricants/moisturizers, hormone replacement therapy for menopause)..."
- Workup
 - ▶ New bullet added: Biopsy ± EUA as clinically indicated
- 4th bullet revised: ~~Consider comprehensive genomic profiling (CGP) via a validated and/or FDA-approved assay~~ *Consider comprehensive molecular profiling as determined by an FDA-approved assay, or a validated test performed in a Clinical Laboratory Improvement Amendments (CLIA)-certified laboratory.*

[CERV-12](#)

- Local/regional recurrence; Therapy for Relapse
 - ▶ No prior RT or failure outside of previously treated field pathway revised: Individualized EBRT ~~± systemic therapy~~ + *concurrent platinum-containing chemotherapy ± brachytherapy*
 - ▶ Prior RT; Central disease:
 - ◊ Revised: In carefully selected patients ~~with small (<2 cm) lesions~~
 - *Individualized EBRT ± concurrent platinum-containing chemotherapy* added as an option
 - ▶ Prior RT; Noncentral disease:
 - ◊ Revised: Individualized EBRT ~~± systemic therapy~~ ± *concurrent platinum-containing chemotherapy*
 - ◊ *Best supportive care ([See NCCN Guidelines for Palliative Care](#))* added as an option.

[CERV-13](#)

- First column revised: Stage IVB or *Recurrence with distant metastases*.
- Amenable to local treatment; Treatment; Revised: "...Local ablative therapies ± individualized EBRT or Individualized EBRT ~~± systemic therapy concurrent platinum-containing chemotherapy~~"
- Not amenable to local treatment; Treatment revised: "Systemic therapy ~~or~~ *and/or* Best supportive care..."
- Footnote dd revised: ~~Consider tumor mutational burden (TMB) testing as determined by a validated and/or FDA-approved assay. Consider comprehensive molecular profiling as determined by an FDA-approved assay, or a validated test performed in a CLIA-certified laboratory.~~

**Updates in Version 1.2024 of the NCCN Guidelines for Cervical Cancer from Version 1.2023 include:****Small Cell Neuroendocrine Carcinoma of the Cervix****CERV-14**

- First column revised
 - ▶ Column header: ~~Additional~~ *Primary Workup*
 - ▶ H&P removed
 - ▶ *Additional* imaging
- Disease confined to the cervix; Tumor > 4 cm; Neoadjuvant chemotherapy pathway revised
 - ◊ Consider ~~interval~~ *radical* hysterectomy
 - ◊ ~~Interval~~ *Radical* hysterectomy not done
 - ◊ ~~Interval~~ *Radical* hysterectomy

CERV-15

- Locally advanced disease (IB3–IVA); Primary Treatment revised: "Chemoradiation + brachytherapy ± ~~adjuvant~~ chemotherapy..."

All Histologies**CERV-A** Principles of Pathology**CERV-A 1 of 7** Squamous Cell Carcinoma, Adenocarcinoma, or Adenosquamous Carcinoma

- Pathologic assessment:
 - ▶ 5th arrow sub-bullet revised: "...progressive, or metastatic ~~disease~~ *cervical carcinoma*; and/or *NTRK* gene fusion testing for patients with cervical sarcoma."
 - ▶ 7th arrow sub-bullet revised: Consider ~~tumor mutational burden (TMB) testing through a validated and/or FDA-approved assay~~ *comprehensive molecular profiling as determined by an FDA-approved assay, or a validated test performed in a CLIA-certified laboratory.*
 - ▶ New arrow sub-bullet added: HER2 immunohistochemistry (IHC) testing (with reflex to HER2 fluorescence in situ hybridization [FISH] for equivocal IHC) is recommended for advanced, metastatic, or recurrent cervical carcinoma.
- New principles pages were added for Squamous Cell Carcinoma, Endocervical adenocarcinoma, and Adenosquamous Carcinoma. ([CERV-A 2 of 7](#) through [CERV-A 5 of 7](#))

CERV-B Principles of Imaging**CERV-B 1 of 4**

- Initial workup; Stage I, Non-Fertility Sparing; 2nd diamond sub-bullet revised: "...chest/abdomen/pelvis CT or *FDG*-PET/MRI for FIGO stage IB1–IB3."
- Footnote a revised through out the section: MRI *is performed with and without contrast* and CT ~~are~~ *is performed with contrast throughout the guidelines* unless contraindicated. Contrast is not required for screening chest CT.

CERV-B 3 of 4

- Small Cell NECC
 - ▶ 1st bullet revised: ~~Additional Workup~~ *Imaging*
 - ▶ Footnote a revised: "MRI *is performed with or without contrast* and CT ~~are~~ *is performed with contrast throughout the guidelines* unless contraindicated..."

Updates in Version 1.2024 of the NCCN Guidelines for Cervical Cancer from Version 1.2023 include:

[CERV-C](#) Principles of Evaluation and Surgical Staging

[CERV-C 1 of 7](#)

- Types of Resection and Appropriateness for Treatment of Cervical Cancer
 - ▶ 2nd bullet revised: "...evaluate for residual disease is recommended, *except during pregnancy*. Cone biopsy..."
- New bullets added:
 - ▶ Select patients with Stage IA2–IB1 disease based on cone biopsy and who meet all the conservative surgery criteria listed below, may be treated with conization or simple hysterectomy with bilateral pelvic lymphadenectomy or sentinel node mapping:
 - ◊ No LVS1
 - ◊ Negative cone margins
 - ◊ Squamous cell (any grade) or usual type adenocarcinoma (grade 1 or 2 only)
 - ◊ Tumor size ≤2 cm
 - ◊ Depth of invasion ≤10 mm
 - ◊ Negative imaging for metastatic disease

[CERV-C 2 of 7](#)

- New bullet added: For patients who experience treatment-related menopause, ovarian preservation or transposition should be considered when feasible.

[CERV-D](#) Principles of Radiation Therapy

[CERV-D 1 of 9](#)

General Principles

- 1st bullet revised: "...surgically staged, *FDG*-PET imaging..."
- New Bullet added: IMRT technique is preferred to minimize toxicities in definitive treatment of the pelvis with or without para-aortic treatment. Regular use of image-guided radiation therapy (IGRT) with orthogonal imaging and/or routine volumetric imaging (such as cone beam CT) at the time of treatment delivery, is essential to ensure appropriate coverage of targets and sparing of normal tissues.
- 4th bullet revised: "Brachytherapy is a critical component of definitive ~~therapy~~ *RT* for all patients with primary cervical cancer ~~who are not candidates for surgery...~~"

Updates in Version 1.2024 of the NCCN Guidelines for Cervical Cancer from Version 1.2023 include:

[CERV-D](#) Principles of Radiation Therapy-continued

[CERV-D 2 of 9](#)

- General Treatment Information

- ▶ Treatment Information - External Beam

- ◊ New bullet added: IMRT technique can reduce acute and chronic gastrointestinal and hematologic toxicity
- ◊ 5th bullet revised: "... an SIB target may be boosted up to approximately 2.10 to 2-2 2.3 Gy/fraction, depending..."

[CERV-D 3 of 9](#)

- Posthysterectomy Adjuvant Radiation Therapy; New bullet added: Consider Vaginal cuff brachytherapy for positive or close vaginal margins.
- New section added for *Re-irradiation*

[CERV-D 4 of 9](#)

- General Treatment Information; Treatment Information - Brachytherapy:

- ▶ 1st bullet revised: "Brachytherapy is a critical component of definitive therapy RT for all patients with primary cervical cancer who are not candidates for surgery. This is usually performed..."
- ▶ New bullet added: Consider the use of intraprocedural imaging when placing brachytherapy applicators for intact cervical cancer.

[CERV-D 9 of 9](#)

- References updated to include: Chino J, Annunziata CM, Beriwal S, et al. Radiation Therapy for Cervical Cancer: Executive Summary of an American Society for Radiation Oncology Clinical Practice Guideline. *Pract Radiat Oncol.* 2020;10:220-234.

[CERV-F](#) Systemic Therapy for Cervical Cancer

[CERV-F 1 of 3](#) Squamous Cell Carcinoma, Adenocarcinoma, or Adenosquamous Carcinoma

- Chemoradiation

- ▶ New section added:

- ◊ Other Recommended Regimens (if cisplatin and carboplatin are unavailable)
 - Capecitabine/mitomycin
 - Gemcitabine
 - Paclitaxel

- Recurrent or Metastatic Disease

- ▶ First-line Therapy: Section reformatted to denote PD-L1-positive tumors as a separate bullet

- ▶ Second-line or Subsequent Therapy

- ◊ Preferred Regimens: Cemiplimab added
- ◊ Other Recommended Regimens: Irinotecan changed from category 2B to category 2A
- ◊ Useful in Certain Circumstances
 - Section revised to separate out regimens by mutation type
 - Fam-trastuzumab deruxtecan-nxki added for HER2-positive tumors (IHC 3+ or 2+)
 - NTRK gene fusion-positive tumors: Single agent Larotrectinib and Entrectinib changed from category 2B to category 2A.

Updates in Version 1.2024 of the NCCN Guidelines for Cervical Cancer from Version 1.2023 include:

[CERV-F](#) Systemic Therapy for Cervical Cancer-continued

[CERV-F 1A of 3](#)

- Footnote b revised: "Cost and toxicity, *especially when using extended field RT*, should be carefully considered..."
- New footnote c added: These agents may be considered when cisplatin and carboplatin are unavailable.
- Footnote g revised: Recommended in patients whose tumors express PD-L1 (CPS ≥ 1) as determined by an ~~FDA-approved test~~ *FDA-approved assay, or a validated test performed in a CLIA-certified laboratory.*
- Footnote h is new: Checkpoint inhibitors and/or monoclonal antibodies included in this regimen may be continued as maintenance therapy. Refer to the original study protocol for maintenance therapy dosing schedules.
- Footnote i revised: "... as determined by a ~~validated and/or FDA-approved test~~ *an FDA-approved assay, or a validated test performed in a CLIA-certified laboratory*, that have progressed following prior treatment and who have no satisfactory alternative treatment options.

[CERV-F 2 of 3](#)

- Small Cell NECC
 - ▶ Recurrent or Metastatic Disease
 - ◇ Second-line or Subsequent Therapy; Other Recommended Regimens: Irinotecan changed from category 2B to category 2A
 - ▶ Footnote f added: [NCCN Guidelines for the Management of Immunotherapy-Related Toxicities](#).

[CERV-F 3 of 3](#)

- References updated to reflect changes in the regimen tables.

[CERV-G](#) Principles Of Gynecologic Survivorship

- Physical Effects; New bullet added: Prior pelvic RT may contribute to bone loss and increase the risk of pelvic fractures. Consider bone density testing and prophylactic use of bisphosphonates, particularly in patients with osteoporosis.
- Clinical approach; 4th Bullet revised: ~~For premenopausal patients, hormone replacement therapy should be considered.~~ *For treatment-related menopause, hormone therapy should be considered.*

[ABBR-1](#) and [ABBR-2](#)

- Abbreviations updated to reflect new recommendations in the algorithm.

WORKUP

- History and physical (H&P)
- Complete blood count (CBC) (including platelets)
- Cervical biopsy, pathologic review^a
- Cone biopsy as indicated^b
- Liver function test (LFT)/renal function studies
- Imaging^c
- Smoking cessation and counseling intervention, if indicated (See [NCCN Guidelines for Smoking Cessation](#))
- Consider HIV testing^d
- Consider examination under anesthesia (EUA) cystoscopy/proctoscopy^e (≥ stage IB3)
- Consider options for fertility sparing or referral to reproductive endocrinology and infertility (REI) specialist

Squamous cell cancer, adenocarcinoma, or adenosquamous carcinoma

Small cell neuroendocrine carcinoma of the cervix (NECC)

CLINICAL STAGE

Stage IA1

Stage IA2

Stage IB1

Stage IB2

Stage IIA1

Stage IB3

Stage IIA2

Stage IIB

Stage III

Stage IVA

Stage IVB

Incidental finding of invasive cancer at simple (extrafascial) hysterectomy

Primary Treatment (Fertility Sparing) ([CERV-2](#))

Primary Treatment (Non-Fertility Sparing) ([CERV-3](#))

Primary Treatment (Fertility Sparing) ([CERV-2](#))

Primary Treatment (Non-Fertility Sparing) ([CERV-3](#)) and ([CERV-4](#))

Primary Treatment ([CERV-4](#))

Primary Treatment ([CERV-4](#)) and ([CERV-6](#))

Primary Treatment ([CERV-6](#))

Treatment ([CERV-13](#))

Treatment ([CERV-9](#))

Primary Workup ([CERV-14](#))

All staging in guidelines is based on updated 2018 FIGO staging. ([ST-1](#))

^a [Principles of Pathology \(CERV-A\)](#).

^b See [Discussion](#) for indications for cone biopsy.

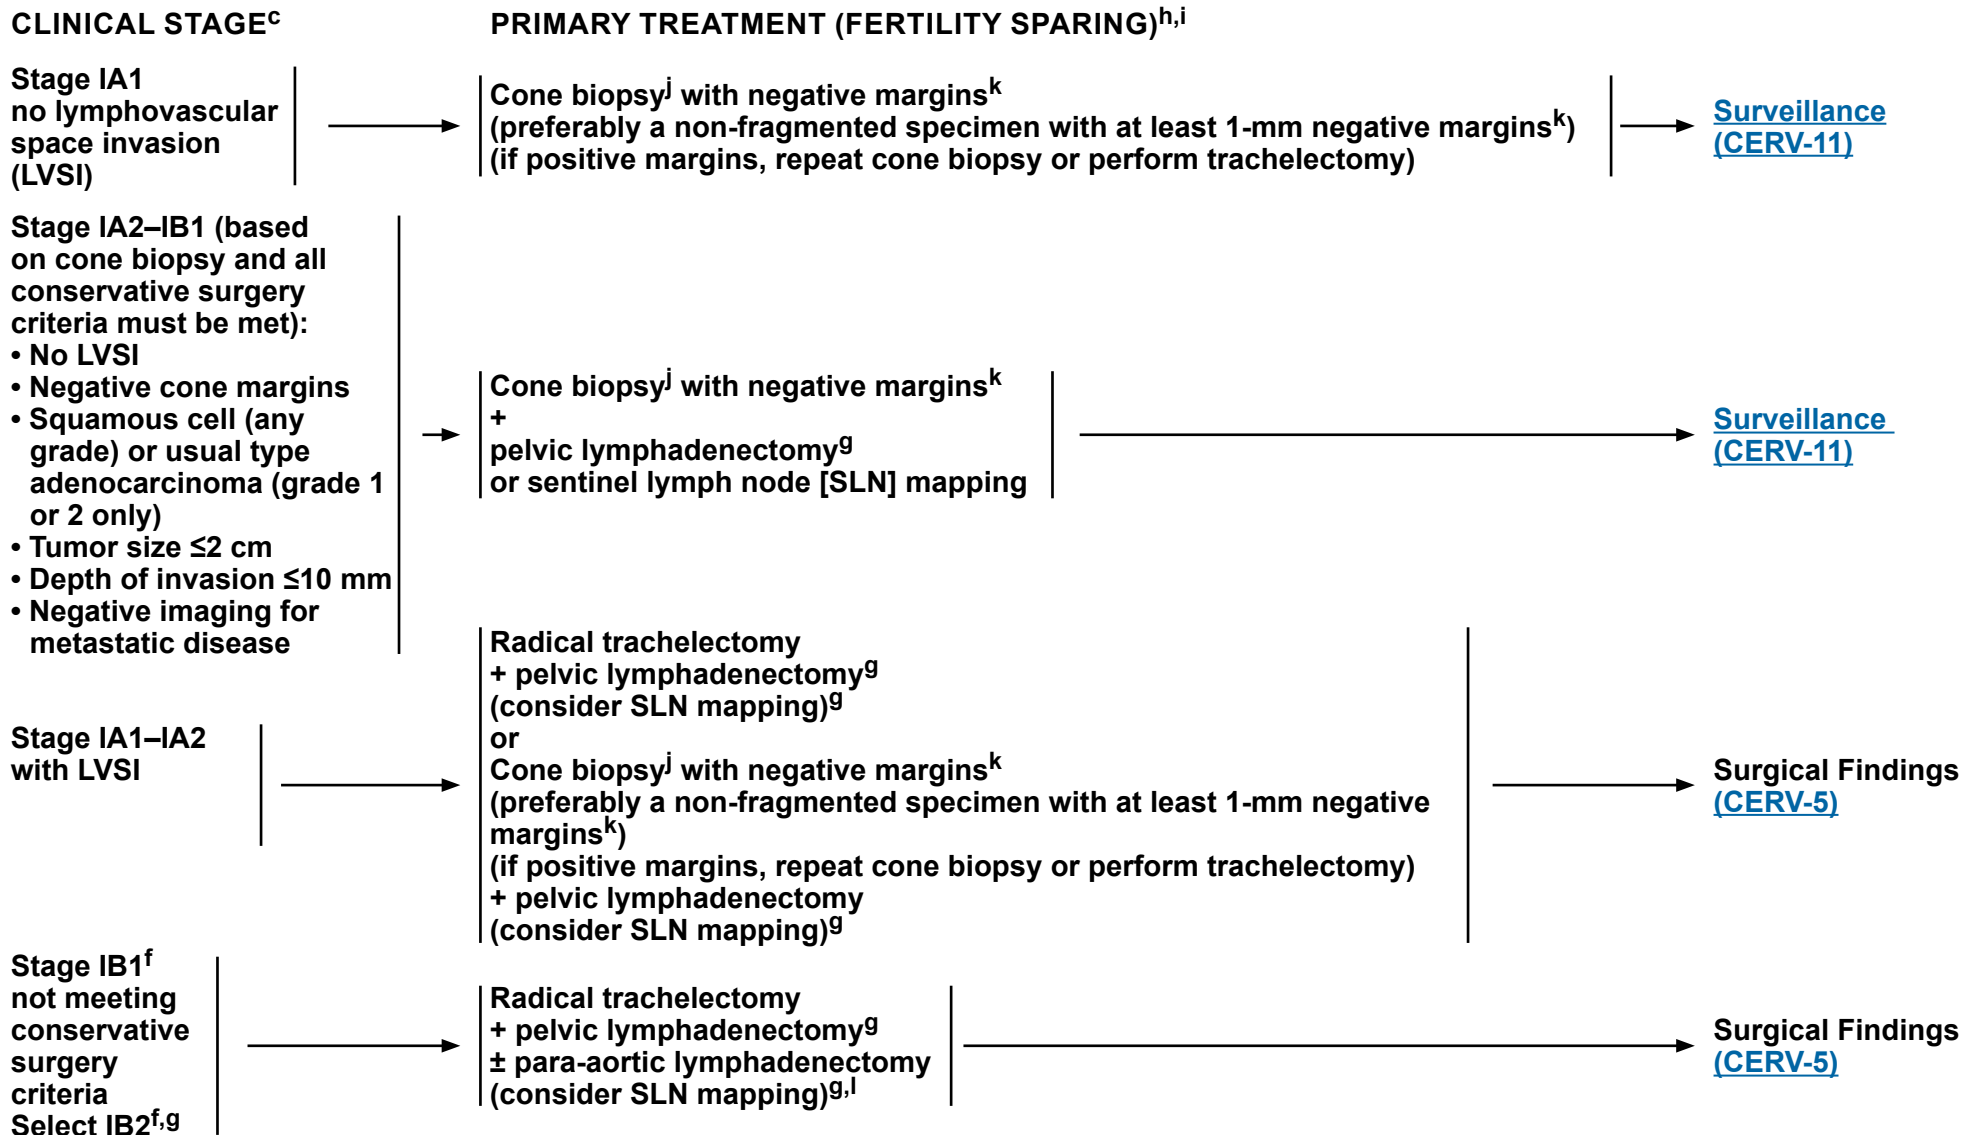

^c [Principles of Imaging \(CERV-B\)](#).

^d Consider HIV testing, especially in younger patients. Patients with cervical cancer and HIV should be referred to an HIV specialist and should be treated for cervical cancer as per these guidelines. Modifications to cancer treatment should not be made solely on the basis of HIV status.

^e For suspicion of bladder/bowel involvement, cystoscopy/proctoscopy with biopsy is required.

Note: All recommendations are category 2A unless otherwise indicated.

Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.

Footnotes on CERV-2A

Note: All recommendations are category 2A unless otherwise indicated.
Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.

FOOTNOTES FOR [CERV-2](#)

^c [Principles of Imaging \(CERV-B\)](#).

^f Fertility-sparing surgery for stage IB has been most validated for tumors ≤ 2 cm. For stage IB2 lesions 2–4 cm, abdominal approach is favored. Small cell neuroendocrine histology and gastric type adenocarcinoma are not considered suitable tumors for this procedure.

^g [Principles of Evaluation and Surgical Staging \(CERV-C\)](#).

^h There are no data to support a fertility-sparing approach in small neuroendocrine tumors or gastric type adenocarcinoma. Total hysterectomy after completion of childbearing is at the patient's and surgeon's discretion, but is strongly advised in patients with continued abnormal pap smears or chronic persistent HPV infection.

ⁱ Consultation with REI experts is suggested.

^j Cold knife conization (CKC) is the preferred method of diagnostic excision, but loop electrosurgical excision procedure (LEEP) is acceptable, provided adequate margins and proper orientation are obtained. Endocervical curettage (ECC) above the excision should be added except in pregnancy.

^k Negative for invasive disease or histologic high-grade squamous intraepithelial lesion (HSIL) at margins.

^l For SLN mapping, the best detection rates and mapping results are in tumors < 2 cm.

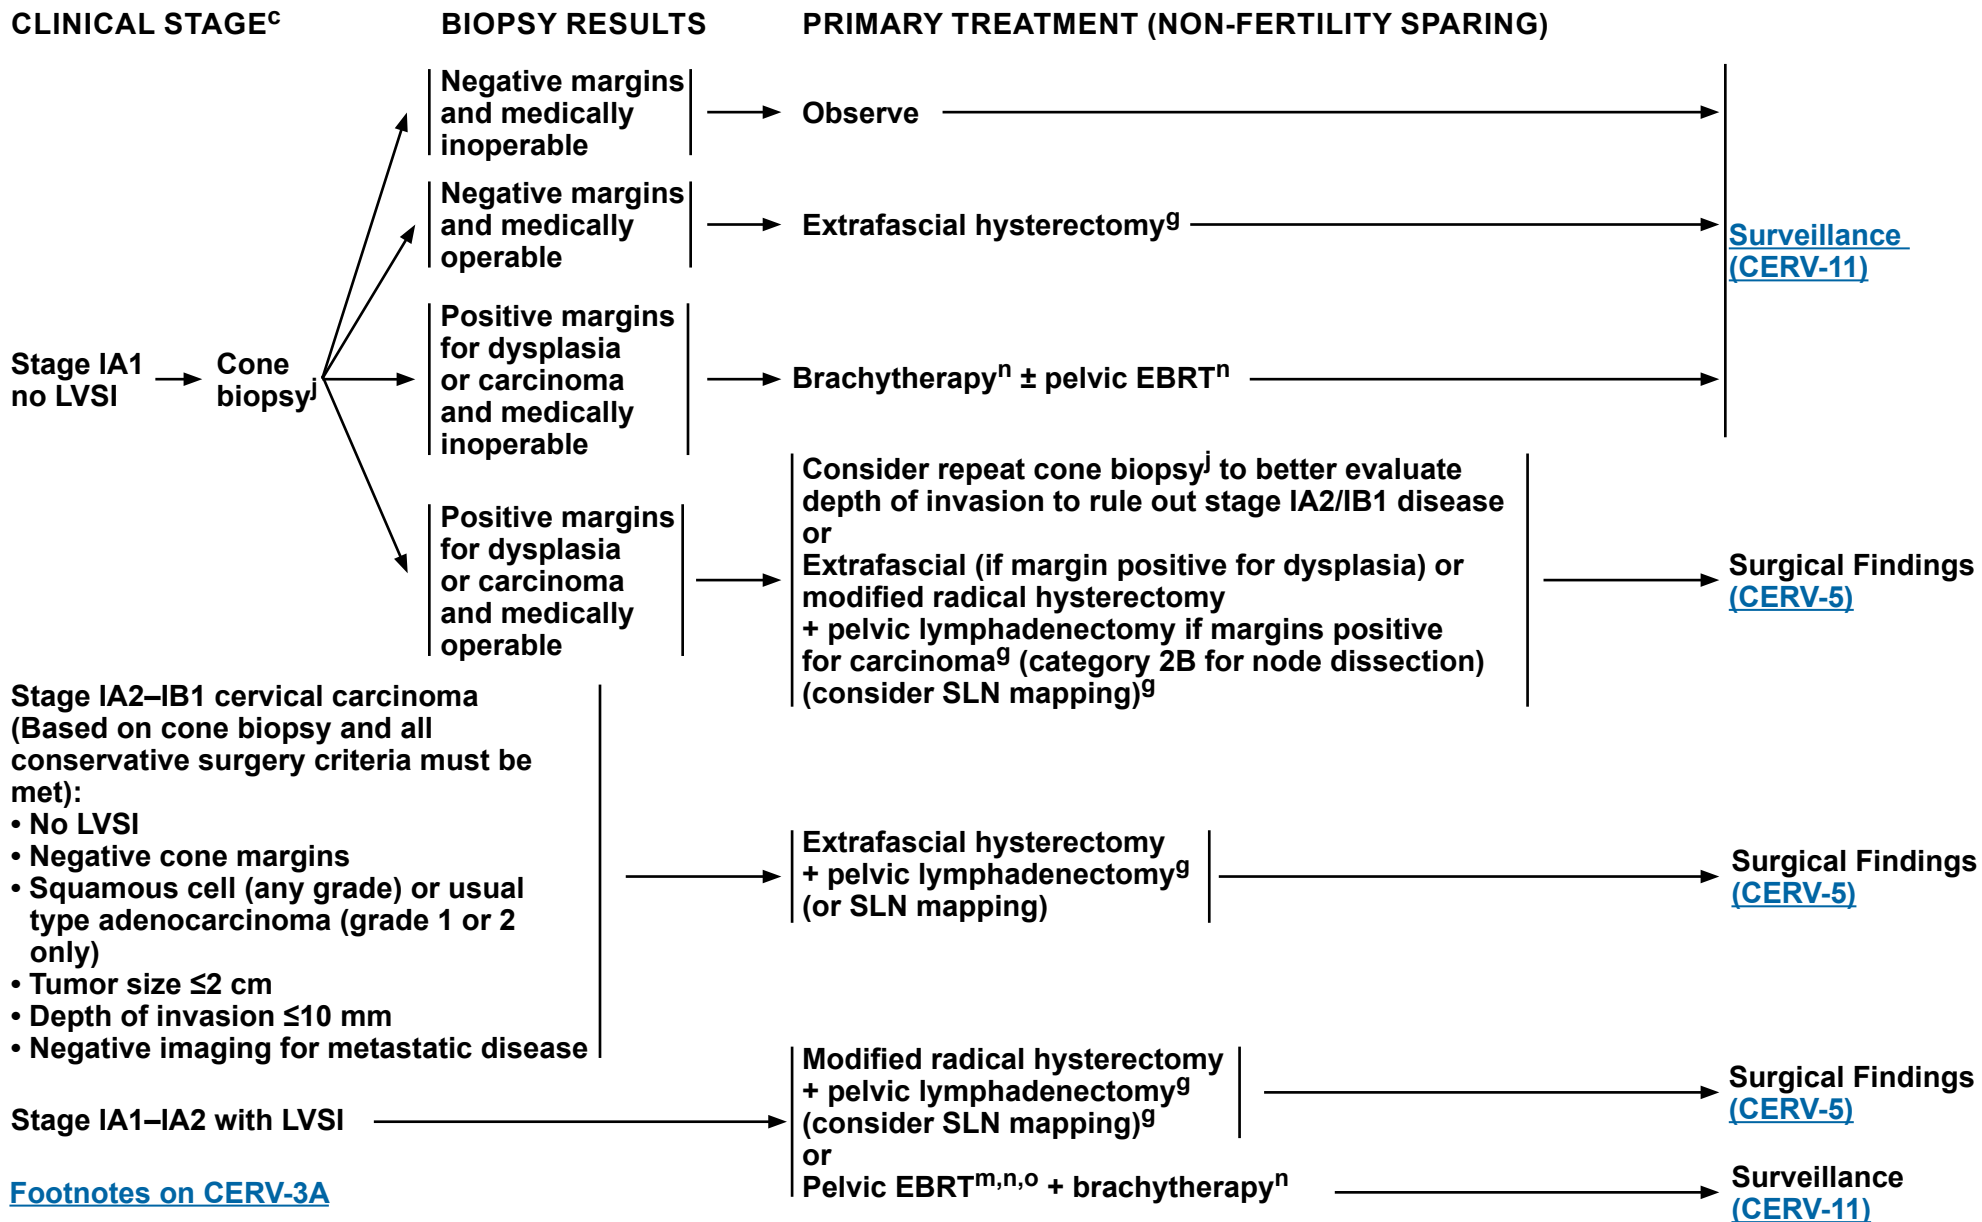

Note: All recommendations are category 2A unless otherwise indicated.

Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.

NCCN Guidelines Version 3.2024

Cervical Cancer

**PRINCIPLES OF PATHOLOGY¹****Squamous Cell Carcinoma, Adenocarcinoma, or Adenosquamous Carcinoma****• Procedure**

- ▶ Radical hysterectomy

• Pathologic assessment:

- ▶ Uterus
 - ◇ Hysterectomy type (where applicable)
 - ◇ Tumor site
 - ◇ Tumor size, including greatest dimension and additional two dimensions
 - ◇ Histologic type^a
 - ◇ Histologic grade
 - ◇ Stromal invasion (depth of invasion in mm/cervical wall thickness in mm)^b
 - ◇ Tumor width extent in mm
 - ◇ Surgical resection margin status
 - If negative, include closest margin and distance to closest margin (in mm)^c
 - If positive, include location of positive margin^c
 - ◇ LVSI (does not impact FIGO 2018 staging¹)
- ▶ Other tissue/organ involvement (parametrium, vaginal cuff, fallopian tubes, ovaries, peritoneum, omentum, other)
- ▶ Lymph nodes (when resected)
 - ◇ SLNs should undergo ultrastaging for detection of low-volume metastasis^d
 - ◇ Non-SLNs do not require ultrastaging and can be processed as per routine protocols
 - ◇ Include the number of lymph nodes with isolated tumor cells, micrometastasis, and macrometastasis
 - ◇ Isolated tumor cells are noted as pN0(i+)
- ▶ Recommend PD-L1 testing for patients with recurrent, progressive, or metastatic disease
- ▶ Recommend mismatch repair (MMR)/microsatellite instability (MSI) testing for patients with recurrent, progressive, or metastatic cervical carcinoma; and/or *NTRK* gene fusion testing for patients with cervical sarcoma^{3,4}
- ▶ Recommend human papillomavirus (HPV) status on all cervical adenocarcinomas. HPV in situ hybridization (ISH) or molecular testing is preferred, but p16 may be acceptable if HPV testing is not available.
- ▶ Consider comprehensive molecular profiling as determined by an FDA-approved assay, or a validated test performed in a CLIA-certified laboratory.⁵
- ▶ HER2 immunohistochemistry (IHC) testing (with reflex to HER2 fluorescence in situ hybridization [FISH] for equivocal IHC) is recommended for advanced, metastatic, or recurrent cervical carcinoma.
- ▶ Consider *RET* gene fusion testing for patients with locally advanced or metastatic cervical cancer

^a According to the 2018 International Endocervical Adenocarcinoma Criteria and Classification (IECC),⁶ morphologic features (luminal mitotic figures and apoptosis) can be used to distinguish between HPV-associated endocervical adenocarcinomas and HPV-independent adenocarcinomas. Tumors can be further subtyped based on morphologic features.

^b Evaluation of histologic pattern of invasion for endocervical adenocarcinomas is an emerging concept.^{7,8,9} Three clinically significant histologic patterns of invasion for endocervical adenocarcinoma have been described. Tumors with so-called pattern A invasion (defined by well-demarcated glands with round contours, an absence of single cells, an absence of desmoplastic stromal response, and no lymphatic vascular invasion) have excellent survival and do not have lymph node metastases or recurrences.⁷

^c While reporting of this information is not required, knowledge of this information is useful for multidisciplinary treatment planning.

^d Ultrastaging commonly entails serial sectioning of the SLN and review of multiple hematoxylin and eosin (H&E)-stained sections with or without cytokeratin IHC for all blocks of the SLN. There is not a standard protocol for lymph node ultrastaging.

Note: All recommendations are category 2A unless otherwise indicated.

Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.

[References](#)[Continued](#)

PRINCIPLES OF PATHOLOGY

Squamous Cell Carcinoma

General Principles

- Cervical squamous cell carcinoma (SCC) is a squamous epithelial tumor with stromal invasion and/or exophytic invasion.
- It accounts for approximately 80%–90% of cervical carcinomas worldwide
- Majority of cervical SCCs (>90%) are HPV-associated, with HR-HPV 16 and 18 being the most common types.
- HPV-independent squamous cell carcinoma of the cervix is a relatively recently described entity, with 5%–7% of cervical SCCs reported to be HPV-negative.
- HPV-independent SCC typically present later in life (7th decade) and at an advanced stage
- HPV-independent cervical SCCs have been described to demonstrate TP53, KRAS, ARID1A, and PTEN mutations.

Histology

- Squamous cell carcinomas demonstrate infiltrating and angulated epithelial nests, often showing paradoxical maturation, in a background of inflammation and stromal desmoplastic response.
- Histologic patterns of SCC include keratinizing (presence of keratin pearls), non-keratinizing, basaloid (nests of basal-type squamous cells), warty (condylomatous), and papillary types.
 - ▶ Non-keratinizing and basaloid patterns are the most commonly noted with HPV-associated tumors, while HPV-independent SCC are usually of the keratinizing type.
 - ▶ Of note, morphology alone is unreliable and utility of p16 IHC and/or molecular HPV typing is recommended for establishing HPV-association.
 - ◇ Almost all HPV-associated SCCs show strong and diffuse p16 overexpression in nuclei and cytoplasm by IHC.

Note: All recommendations are category 2A unless otherwise indicated.

Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.

CERV-A
2 OF 7

PRINCIPLES OF PATHOLOGY

Endocervical Adenocarcinoma

General Principles

- Endocervical adenocarcinoma is a gland forming tumor typically originating in the transformation zone, demonstrating stromal invasion and/or expansile type invasion.
- Adenocarcinomas of the cervix can be HPV-associated (HR-HPV types 18, 16, and 45 most commonly) or HPV-independent.
- Determining the HPV status is recommended as HPV-associated endocervical adenocarcinomas have shown better clinical outcomes compared with HPV-independent adenocarcinomas.
- Grossly, endocervical adenocarcinomas may present as ulceration, exophytic masses, or as barrel-shaped cervix when endophytic growth is present.

Note: All recommendations are category 2A unless otherwise indicated.

Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.

CERV-A
3 OF 7

**PRINCIPLES OF PATHOLOGY****Endocervical Adenocarcinoma** (continued)**Histologic subtypes**

- **HPV-associated adenocarcinoma:** Include usual type, which accounts for approximately 75% of cases and includes villoglandular and micropapillary subtypes, and mucinous types, which include intestinal, signet-ring cell, and invasive stratified mucin-producing carcinoma (invasive SMILE).
 - ▶ **95% of HPV-associated carcinomas will demonstrate block-type p16 expression by IHC.** Of note, endometrial carcinomas (high grade endometrioid, serous and clear cell carcinomas) can also express p16; rarely p16 negative cases can occur from methylation-induced activation; and results of p16 were shown to be not as reproducible when performed on older or poorly preserved tissue blocks.
 - ▶ **When available, HR-HPV ISH can be utilized, as it is as sensitive and more specific than p16 IHC.**
 - ▶ **While PCR can confirm HPV infection, it has lower sensitivity and specificity, and does not provide ascertainment that HPV is present within the neoplastic cells.**
 - ▶ **The Silva system is utilized for evaluating patterns of invasion in HPV-associated endocervical adenocarcinoma, subdividing these tumors into three categories:**
 - ◊ **Silva Pattern A – non-destructive invasion; well demarcated rounded glands without solid growth, single stromal cells, desmoplastic stromal response or LVSI. These tumors have excellent survival, without lymph node metastasis or recurrence.**
 - ◊ **Silva Pattern B – localized (early) destructive stroma invasion, arising from well-demarcated glands; may show small glands or individual cells in a focally desmoplastic stroma with or without LVSI, and without solid growth.**
 - ◊ **Silva Pattern C – diffuse destructive stromal invasion, solid growth or poorly differentiated component, with or without LVSI**
- **HPV-independent endocervical adenocarcinomas:** Include gastric, clear cell, mesonephric and endometrioid types.
 - ▶ **Gastric type makes up approximately 10%–15% of cervical adenocarcinomas (with up to 25% noted in Japan). It is found in association with Peutz-Jeghers syndrome (STK11 mutation), and while typically negative for p16 block expression, it may show mutated p53 expression in approximately 50% of cases. These tumors show a high prevalence of invasion, extrauterine spread and present at an advanced stage.**
 - ▶ **Mesonephric type demonstrates mesonephric (Wolffian) differentiation and is associated with mesonephric remnants. It typically is located deep in the lateral wall and histologically demonstrates architectural crowding, haphazard infiltration, atypia, mitotic activity, and necrosis. GATA-3 and CD10 IHC stains will be positive in the tumor and associated mesonephric remnants.**
 - ▶ **Clear cell carcinomas make up 3%–4% of endocervical adenocarcinomas, occurring sporadically or in association with in-utero diethylstilbestrol (DES) exposure. These tumors may demonstrate diffuse p16 expression despite the absence of HPV infection. In these instances, HR-HPV ISH can be utilized.**
 - ▶ **Endometrioid carcinoma is quite uncommon, approximating 1% of primary endocervical adenocarcinomas, and may present in the setting of endometriosis; however, a primary endometrial carcinoma must be ruled out.**
 - ◊ **Utilizing a panel of immunohistochemical stains (vimentin, ER, p16, and monoclonal CEA) may be helpful in differentiating between endocervical and endometrial carcinoma. Typically, endometrioid adenocarcinoma will express vimentin and ER, while endocervical adenocarcinoma is positive for mCEA and p16 (when HPV-associated).**

Note: All recommendations are category 2A unless otherwise indicated.

Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.

[Continued](#)**CERV-A**
4 OF 7

PRINCIPLES OF PATHOLOGY

Adenosquamous Carcinoma

General Principles

- Epithelial tumor with squamous and glandular differentiation
- Accounts for approximately 5%–6% of all cervical carcinomas
- Clinical outcomes are similar to cervical adenocarcinoma

Histology

- The tumor components (squamous and glandular) should be admixed and be able to be discerned on routine histology
- The squamous component typically demonstrates abundant glycogen-rich (clear) cytoplasm, while the gland forming component is often of usual HPV-associated adenocarcinoma

Immunohistochemistry (IHC)

- IHC for p16 usually shows overexpression in both components
- Additional IHC stains such as CK7, CEA, and PAX8 may be utilized to highlight the glandular component, while p63 and p40 highlight the squamous component

Note: All recommendations are category 2A unless otherwise indicated.

Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.

**PRINCIPLES OF PATHOLOGY¹⁰⁻¹³****Neuroendocrine Carcinoma of the Cervix (NECC)****• Histologic description**

- ▶ Although rare, comprising <5% of cervical cancers, the cervix is the most common site for neuroendocrine carcinoma (eg, small cell and large cell neuroendocrine carcinoma) in the genital tract.
- ▶ NECC is clinically aggressive, with rapid metastasis and a frequently poor clinical outcome.
- ▶ NECC is usually HPV-associated; types 16 and 18 are the most common (18 more often than 16).
- ▶ This carcinoma type morphologically resembles neuroendocrine carcinomas of the lung.
- ▶ Small cell NECC is a morphologic diagnosis regardless of IHC staining profile.
- ▶ The predominant growth pattern is diffuse. Additional growth patterns include insular (solid nests/islands of cells with peripheral palisading and retraction of stroma), as well as perivascular and thick trabeculae with serpiginous (wavy) growth. Pseudoglandular and rosette-like structures are variably present.
- ▶ Cytologic features include a uniform population of cells with indistinct cell borders, scant cytoplasm, and hyperchromatic nuclei with fine granular chromatin. Abundant mitotic activity and apoptotic debris is common. Nuclear molding and indistinct nucleoli are additional features. Necrosis is common.
- ▶ Associated cervical glandular lesions (pre- or overtly malignant) may be seen. Consider diagnoses such as adenocarcinoma mixed with neuroendocrine carcinoma as appropriate.
- ▶ Differentiating between small cell and large cell NECC may be difficult.

• Immunohistochemistry (IHC)

- ▶ Small cell NECC is variably positive for chromogranin, CD56, and synaptophysin.
 - ◊ CD56 and synaptophysin are the most sensitive neuroendocrine markers, but CD56 lacks specificity.
 - ◊ Chromogranin is the most specific neuroendocrine marker, but lacks sensitivity with only about 50%–60% of small cell NECC being positive.^{14,15}
 - ◊ Insulinoma-associated protein 1 (INSM1) and synaptophysin are other neuroendocrine markers, with 80% and 70% positivity, respectively.^{14,15}
- ▶ If the tumor demonstrates classic morphologic features of small cell NECC, the diagnosis can be made in the absence of IHC neuroendocrine positivity (this is NOT true for large cell NECC).
- ▶ Small cell NECC may be only focally positive (often punctuate cytoplasmic staining) or even negative with broad-spectrum cytokeratins.
- ▶ A high percentage of primary NECCs are thyroid transcription factor-1 (TTF1)-positive, including some with diffuse immunoreactivity, and this marker is of no value in distinction from a pulmonary metastasis.
- ▶ Most NECCs are diffusely positive for p16 due to the presence of high-risk HPV. However, p16 positivity cannot be used to aid in determining the site of origin; neuroendocrine carcinomas arising at other sites may strongly express p16 due to a non-HPV-related process. Consider HPV ISH or polymerase chain reaction (PCR) testing.
- ▶ Peptide hormones, including ACTH, serotonin, somatostatin, calcitonin, glucagon, and gastrin, have been demonstrated in some high-grade NECCs.

Note: All recommendations are category 2A unless otherwise indicated.

Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.

PRINCIPLES OF IMAGING^{a,1-9}

Initial Workup

• Stage I

▶ Non-Fertility Sparing

- ◇ Consider pelvic MRI with contrast to assess local disease extent (preferred for FIGO stage IB1–IB3).
- ◇ Neck/chest/abdomen/pelvis/groin FDG-PET/CT (preferred) or chest/abdomen/pelvis CT or FDG-PET/MRI for FIGO stage IB1–IB3.
- ◇ For patients who underwent TH with incidental finding of cervical cancer, consider neck/chest/abdomen/pelvis/groin FDG-PET/CT or chest/abdomen/pelvis CT to evaluate for metastatic disease and pelvic MRI to assess pelvic residual disease.
- ◇ Other imaging should be based on symptomatology and clinical concern for metastatic disease.^b

▶ Fertility Sparing

- ◇ Pelvic MRI (preferred) to assess local disease extent and proximity of tumor to internal cervical os; perform pelvic transvaginal ultrasound if MRI is contraindicated.
- ◇ Neck/chest/abdomen/pelvis/groin FDG-PET/CT (preferred) or chest/abdomen/pelvis CT in FIGO stage IB1–IB3.
- ◇ Consider chest CT with or without contrast.
- ◇ Other imaging should be based on symptomatology and clinical concern for metastatic disease.^b

• Stage II–IVA

- ▶ Pelvic MRI with contrast to assess local disease extent (preferred).
- ▶ Neck/chest/abdomen/pelvis/groin FDG-PET/CT (preferred) or chest/abdomen/pelvis CT to evaluate for metastatic disease.
- ▶ Other initial imaging should be based on symptomatology and clinical concern for metastatic disease.^c
- ▶ For patients who underwent TH with incidental finding of cervical cancer, consider neck/chest/abdomen/pelvis/groin FDG-PET/CT or chest/abdomen/pelvis CT to evaluate for metastatic disease and pelvic MRI with contrast to assess pelvic residual disease.
- ▶ If first post-treatment FDG-PET/CT is indeterminate, then consider repeating in 3 months.

^a MRI is performed with and without contrast and CT is performed with contrast unless contraindicated. Contrast is not required for screening chest CT.

^b These factors may include abnormal physical exam findings or pelvic, abdominal, or pulmonary symptoms.

^c These factors may include abnormal physical exam findings, bulky pelvic tumor (>4 cm), delay in presentation or treatment, and pelvic abdominal or pulmonary symptoms.

Note: All recommendations are category 2A unless otherwise indicated.

Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.

PRINCIPLES OF IMAGING^{a,1-9}

Follow-up/Surveillance

- **Stage I**
 - ▶ **Non-Fertility Sparing**
 - ◇ Imaging should be based on symptomatology and clinical concern for recurrent/metastatic disease.^b
 - ◇ For patients with FIGO stage IB3 or patients who required postoperative adjuvant radiation or chemoradiation due to high-risk factors,^d a neck/chest/abdomen/pelvis/groin FDG-PET/CT may be performed at 3–6 months after completion of treatment.
 - ▶ **Fertility Sparing**
 - ◇ Consider pelvic MRI with contrast 6 months after surgery and then yearly for 2–3 years.
 - ◇ Other imaging should be based on symptomatology and clinical concern for recurrent/metastatic disease.^b
- **Stage II–IV**
 - ▶ Neck/chest/abdomen/pelvis/groin FDG-PET/CT (preferred) or chest/abdomen/pelvic CT with contrast within 3–6 months of completion of therapy.
 - ▶ Consider pelvic MRI with contrast at 3–6 months post completion of therapy.
 - ▶ Other imaging should be based on symptomatology and clinical concern for recurrent/metastatic disease.^e
- **Stage IVB or Recurrence**
 - ▶ Imaging as appropriate (CT, MRI, or FDG-PET/CT) to assess response or determine further therapy.
- If first post-treatment FDG-PET/CT is indeterminate, then consider repeating in 3 months.

Suspected Recurrence or Metastasis

- Neck/chest/abdomen/pelvis/groin FDG-PET/CT.
- Consider pelvic MRI.

^a MRI is performed with and without contrast and CT is performed with contrast unless contraindicated. Contrast is not required for screening chest CT.

^b These factors may include abnormal physical exam findings or pelvic, abdominal, or pulmonary symptoms.

^d Risk factors may include positive nodes, positive parametria, positive margins, or local cervical factors ([See Sedlis Criteria CERV-E](#)).

^e These factors may include abnormal physical exam findings such as palpable mass or adenopathy, or new pelvic, abdominal, or pulmonary symptoms.

Note: All recommendations are category 2A unless otherwise indicated.

Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.

PRINCIPLES OF IMAGING^{a,1-9}

Small Cell NECC

• **Additional Imaging**

- ▶ Neck/chest/abdomen/pelvis/groin FDG-PET/CT + brain MRI (preferred)
or
- ▶ Chest/abdomen/pelvis CT + brain MRI

• **Treatment Response Assessment**

- ▶ If primary treatment is chemoradiation, then neck/chest/abdomen/pelvis/groin FDG-PET/CT ± brain MRI (preferred) or chest/abdomen/pelvis CT ± brain MRI
- ▶ If neoadjuvant chemotherapy is used, consider reassessment to rule out metastatic disease prior to chemoradiation and brachytherapy

• **Surveillance**

- ▶ Neck/chest/abdomen/pelvis/groin FDG-PET/CT ± brain MRI (preferred)
or
- ▶ Chest/abdomen/pelvis CT ± brain MRI

^a MRI is performed with or without contrast and CT is performed with contrast unless contraindicated. Contrast is not required for screening chest CT.

Note: All recommendations are category 2A unless otherwise indicated.

Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.

**PRINCIPLES OF EVALUATION AND SURGICAL STAGING^a****Types of Resection and Appropriateness for Treatment of Cervical Cancer**

- Treatment of cervical cancer is stratified by stage as delineated in the Guidelines.
- Microinvasive disease, defined as FIGO stage IA1 with no LVSI, has less than a 1% chance of lymphatic metastasis and may be managed conservatively with cone biopsy for preservation of fertility (with negative margins) or with simple hysterectomy when preservation of fertility is not desired or relevant. The intent of a cone biopsy is to remove the ectocervix and endocervical canal en bloc using a scalpel. This provides the pathologist with an intact, non-fragmented specimen without electrosurgical artifact, which facilitates margin status evaluation. If a loop electrosurgical excision procedure (LEEP) is chosen for treatment, the specimen should not be fragmented, and care must be undertaken to minimize electrosurgical artifact at the margins. The shape and depth of the cone biopsy may be tailored to the size, type, and location of the neoplastic lesion. For example, if there is concern for invasive adenocarcinoma versus adenocarcinoma in situ in the cervical canal, the cone biopsy would be designed as a narrow, long cone extending to the internal os in order not to miss possible invasion in the endocervical canal. Length of the cold cone of at least 10 mm is preferred and can be increased to 18–20 mm in patients who have completed childbearing.¹ Endocervical sampling above the cone apex to evaluate for residual disease is recommended, except during pregnancy. Cone biopsy is indicated for triage and treatment of small cancers where there is no likelihood of cutting across gross neoplasm. In cases of stage IA1 with LVSI, a conization (with negative margins) with pelvic SLN mapping/lymphadenectomy is a reasonable strategy.
- Radical hysterectomy with bilateral pelvic lymphadenectomy (with or without SLN mapping) is the preferred treatment for FIGO stage IA2, IB1, IB2, and select IB3–IIA1 lesions when fertility preservation is not desired. Radical hysterectomy results in resection of much wider margins compared with a simple hysterectomy, including removal of parts of the cardinal and uterosacral ligaments and the upper 1–2 cm of the vagina; in addition, pelvic and sometimes para-aortic nodes are removed. The Querleu and Morrow classification system² is a modern surgical classification that describes degree of resection and nerve preservation in three-dimensional (3D) planes of resection.³ Procedural details for the most commonly used types of hysterectomy are described in Table 1 ([CERV-C 5 of 7](#)).
- The standard and recommended approach for radical hysterectomy is with an open abdominal approach (category 1). A prospective randomized trial⁴ demonstrated that minimally invasive radical hysterectomy was associated with lower rates of disease-free survival (DFS) and overall survival than open abdominal radical hysterectomy. Moreover, two recent epidemiologic studies also demonstrated that minimally invasive radical hysterectomy was associated with shorter overall survival than open surgery among patients with stage IA2–IB1 cervical cancer.⁵ See [Discussion](#) for additional details.
- Select patients with Stage IA2–IB1 disease based on cone biopsy and who meet **all** the conservative surgery criteria listed below, may be treated with conization or simple hysterectomy with bilateral pelvic lymphadenectomy or sentinel node mapping:
 - ▶ No LVSI
 - ▶ Negative cone margins
 - ▶ Squamous cell (any grade) or usual type adenocarcinoma (grade 1 or 2 only)
 - ▶ Tumor size ≤2 cm
 - ▶ Depth of invasion ≤10 mm
 - ▶ Negative imaging for metastatic disease

^a Recommendations by stage are based on the revised 2018 FIGO staging (Bhatla N, Berek JS, Fredes MC, et al. Revised FIGO Staging for carcinoma of the cervix uteri. *Int J Gynecol Obstet* 2019;145:129-135 and Corrigendum to "Revised FIGO Staging for carcinoma of the cervix uteri" [*Int J Gynecol Obstet* 2019;145:129-135] *Int J Gynecol Obstet* 2019;147:279-280). However, trial data cited within this section utilized the 2009 FIGO staging system.

Note: All recommendations are category 2A unless otherwise indicated.

CERV-C
1 OF 7

**PRINCIPLES OF EVALUATION AND SURGICAL STAGING^a****Types of Resection and Appropriateness for Treatment of Cervical Cancer — continued**

- Para-aortic lymphadenectomy for staging is typically done to the level of the inferior mesenteric artery (IMA). The cephalad extent of dissection can be modified based on clinical and radiologic findings.
- The radical vaginal trachelectomy with laparoscopic lymphadenectomy procedure (with or without SLN mapping) offers a fertility-sparing option for carefully selected individuals with stage IA2 or stage IB1 lesions (<2-cm diameter). The cervix, upper vagina, and supporting ligaments are removed as with a type B radical hysterectomy, but the uterine corpus is preserved. In the more than 300 subsequent pregnancies currently reported, there is a 10% likelihood of second trimester loss, but 72% of patients carry their gestation to 37 weeks or more.⁶ The abdominal radical trachelectomy is a reasonable fertility-sparing strategy. It provides larger resection of parametria than the vaginal approach,⁷ is suitable for select stage IB1–IB2 cases, and has been utilized in lesions between 2–4 cm in diameter. The operation mimics a type C radical hysterectomy.^{b,2,3,7-10}
- For patients who experience treatment-related menopause, ovarian preservation or transposition should be considered when feasible.
- Advanced-stage disease, including FIGO stage IIB and above, is not usually treated with hysterectomy, as delineated in the Guidelines. The majority of advanced-stage disease in the United States is treated with definitive chemoradiation. In some countries, select cases of stage IIB may be treated with upfront radical hysterectomy or neoadjuvant chemotherapy followed by radical hysterectomy.
- Recurrent or persistent disease in the central pelvis following radiation therapy may potentially be cured with the pelvic exenteration procedure. Preoperative assessment for exenteration is designed to identify or rule out distant metastasis. If the recurrence is confined to the pelvis, then surgical exploration is carried out. If intraoperative margin and node assessment are negative, then resection of pelvic viscera is completed. Depending on the location of the tumor, resection may include anterior exenteration, posterior exenteration, or total pelvic exenteration. In cases where the location of tumor allows for adequate margins, the pelvic floor and anal sphincter may be preserved as a supralelevator exenteration. [Table 2](#) summarizes the tissues typically removed with differing types of pelvic exenteration ([CERV-C 6 of 7](#)). These are highly complex procedures and should be performed at centers with a high level of expertise for exenteration procedures. Primary pelvic exenteration (without prior pelvic radiation) is restricted to the rare case where pelvic radiation is contraindicated or to patients who received prior pelvic radiation for another indication and then developed a metachronous, locally advanced cervical carcinoma and further radiation therapy is not feasible.

^a Recommendations by stage are based on the revised 2018 FIGO staging (Bhatla N, Berek JS, Fredes MC, et al. Revised FIGO Staging for carcinoma of the cervix uteri. *Int J Gynecol Obstet* 2019;145:129-135 and Corrigendum to "Revised FIGO Staging for carcinoma of the cervix uteri" [*Int J Gynecol Obstet* 2019;145:129-135] *Int J Gynecol Obstet* 2019;147:279-280). However, trial data cited within this section utilized the 2009 FIGO staging system.

PRINCIPLES OF EVALUATION AND SURGICAL STAGING^{a,d}

Sentinel Lymph Node Mapping for Cervical Cancer:

- SLN mapping as part of the surgical management of select stage I cervical cancer is considered in gynecologic oncology practices worldwide. While this technique has been used in tumors up to 4 cm in size, the best detection rates and mapping results are in tumors less than 2 cm.¹¹⁻¹⁵ This simple technique utilizes a direct cervical injection with dye^c or radiocolloid technetium-99 (99Tc) into the cervix, usually at 2 or 4 points as shown in Figure 1 (below). The SLNs are identified at the time of surgery with direct visualization of colored dye; a fluorescent camera is used if indocyanine green (ICG)¹⁶ was used, and a gamma probe is used if 99Tc was used. SLNs following a cervical injection are commonly located medial to the external iliac vessels, ventral to the hypogastric vessels, or in the superior part of the obturator space (Figure 2). SLNs usually undergo ultrastaging by pathologists, which allows for higher detection of micrometastasis that may alter postoperative management.^{4,17}

Figure 1: Options of SLN Cervical Injection Sites^c

Figure 2: SLNs (blue, arrow) After Cervical Injection Are Commonly Located Medial to the External Iliac, Ventral to the Hypogastric, or in the Superior Part of the Obturator Space^c

^a Recommendations by stage are based on the revised 2018 FIGO staging (Bhatla N, Berek JS, Fredes MC, et al. Revised FIGO Staging for carcinoma of the cervix uteri. *Int J Gynecol Obstet* 2019;145:129-135 and Corrigendum to "Revised FIGO Staging for carcinoma of the cervix uteri" [*Int J Gynecol Obstet* 2019;145:129-135] *Int J Gynecol Obstet* 2019;147:279-280). However, trial data cited within this section utilized the 2009 FIGO staging system.

^c In the phase III randomized FILM trial, ICG was shown to be superior to isosulfan blue dye. (Frumovitz M, Plante M, Lee PS, et al. Near-infrared fluorescence for detection of sentinel lymph nodes in women with cervical and uterine cancers (FILM): a randomised, phase 3, multicentre, non-inferiority trial. *Lancet Oncol* 2018;19:1394-1403).

PRINCIPLES OF EVALUATION AND SURGICAL STAGING WHEN SLN MAPPING IS USED

The key to a successful SLN mapping is adherence to the SLN algorithm, which requires the performance of a side-specific lymphadenectomy in cases of failed mapping and removal of any suspicious or grossly enlarged nodes regardless of mapping (Figure 3).

Figure 3: Surgical/SLN Mapping Algorithm for Early-Stage Cervical Cancer^e

H&E: Hematoxylin and eosin staining
LND: Lymphadenectomy
SLN: Sentinel lymph node

PRINCIPLES OF RADIATION THERAPY¹

General Principles

- The use of CT-based treatment planning and conformal blocking is considered the standard of care for EBRT. MRI is the best imaging modality for determining soft tissue and parametrial involvement in patients with advanced tumors. In patients who are not surgically staged, FDG-PET imaging is useful to help define the nodal volume of coverage, and may be useful postoperatively to confirm removal of abnormal nodes.
- RT is directed at sites of known or suspected tumor involvement. EBRT is directed to the pelvis with or without the para-aortic region.
- IMRT technique is preferred to minimize toxicities in definitive treatment of the pelvis with or without para-aortic treatment. Regular use of image-guided radiation therapy (IGRT) with orthogonal imaging and/or routine volumetric imaging (such as cone beam CT) at the time of treatment delivery, is essential to ensure appropriate coverage of targets and sparing of normal tissues.
- Brachytherapy is a critical component of definitive RT for all patients with primary cervical cancer. This is performed using an intracavitary and/or an interstitial approach.
- For the majority of patients who receive EBRT for cervical cancer, concurrent platinum-containing chemotherapy is given during the time of EBRT.
- Optimal results are achieved when treatment is completed within 8 weeks.

General Treatment Information

• Target Volumes

- ▶ Concepts regarding the gross target volume (GTV), clinical target volume (CTV), planning target volume (PTV), organs at risk (OARs), internal organ motion, and dose-volume histogram (DVH) have been defined for use in conformal radiotherapy, especially for intensity-modulated radiation therapy (IMRT).
- ▶ Very careful attention to detail and reproducibility (including consideration of target and normal tissue definitions, patient and internal organ motion, soft tissue deformation, and rigorous dosimetric and physics quality assurance) is required for proper delivery of IMRT and related highly conformal technologies. Routine image guidance, such as cone-beam CT (CBCT), should be used for defining daily internal soft tissue positioning.
- ▶ The volume of EBRT should cover the gross disease (if present), parametria, uterosacral ligaments, sufficient vaginal margin from the gross disease (at least 3 cm), presacral nodes, and other nodal volumes at risk. For patients with negative nodes on surgical or radiologic imaging, the radiation volume should include the entirety of the external iliac, internal iliac, obturator, and presacral nodal basins. For patients deemed at higher risk of lymph node involvement (eg, bulkier tumors; suspected or confirmed nodes confined to the low true pelvis), the radiation volume should be increased to cover the common iliacs as well. In patients with documented common iliac and/or para-aortic nodal involvement, extended-field pelvic and para-aortic radiotherapy is recommended, up to the level of the renal vessels (or even more cephalad as directed by involved nodal distribution). For patients with lower 1/3 vaginal involvement, the bilateral groins should be covered as well.

Note: All recommendations are category 2A unless otherwise indicated.

Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.

PRINCIPLES OF RADIATION THERAPY¹

General Treatment Information—Continued

Treatment Information - External Beam

- EBRT is delivered using multiple conformal fields or intensity-modulated volumetric techniques, such as IMRT/volumetric-modulated arc therapy (VMAT)/tomotherapy.
- IMRT is helpful in minimizing the dose to the bowel and other critical structures in the post-hysterectomy setting² and in treating the para-aortic nodes when necessary. These techniques can also be useful when high doses are required to treat gross disease in regional lymph nodes. However, conformal external beam therapies (such as IMRT or stereotactic body radiation therapy, SBRT) should not be used as routine alternatives to brachytherapy for treatment of central disease in patients with an intact cervix.
- IMRT technique can reduce acute and chronic gastrointestinal and hematologic toxicity.
- A parametrial boost of 5 to 10 Gy can be considered in select cases with bulky parametrial/pelvic sidewall disease after completion of initial whole pelvic radiation.
- IMRT can be planned to deliver a higher dose to gross disease in the lymph nodes, while simultaneously delivering a lower dose to control microscopic disease to the other targets, termed a simultaneous integrated boost (SIB). Using a combination of IMRT with SIB can deliver higher doses to grossly positive nodal disease in a shorter time frame, while sparing normal tissues. In general, an SIB target may be boosted up to approximately 2.10 to 2.3 Gy/fraction, depending on target and OAR volumes. At times, additional external boosts may be necessary. Target doses for nodes can range from 54 to 63 Gy, with strict attention to the contribution from brachytherapy, and respecting normal tissue doses while paying attention to adjacent normal tissue doses.
- SBRT is an approach that allows for delivery of very high doses of focused EBRT in 1–5 fractions and may be applied to isolated metastatic sites; consideration can be given for limited disease in the re-irradiation setting.^{3,4}

Dosing Prescription Regimen - External Beam

- Coverage of microscopic nodal disease requires an EBRT dose of approximately 40–45 Gy (in conventional fractionation of 1.8–2.0 Gy daily possibly with an SIB if IMRT is used), and highly conformal boosts of an additional 10–20 Gy may be considered for limited volumes of gross unresected adenopathy, with consideration of the dose given by brachytherapy. For the majority of patients who receive EBRT for cervical cancer, concurrent platinum-containing chemotherapy is given during the time of EBRT.

Note: All recommendations are category 2A unless otherwise indicated.

Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.

**PRINCIPLES OF RADIATION THERAPY¹****General Treatment Information—Continued****Definitive RT for an Intact Cervix^a**

- In patients with an intact cervix (ie, those who do not have surgery), the primary tumor and regional lymphatics at risk are typically treated with definitive EBRT to a dose of approximately 45 Gy (40–50 Gy). The volume of the EBRT would depend on the nodal status as determined surgically or radiographically (as previously described). The primary cervical tumor is then boosted, using brachytherapy, with an additional 30 to 40 Gy using either image guidance (preferred) or to point A (in low dose-rate [LDR] equivalent dose), for a total point A dose (as recommended in the guidelines) of 80 Gy for small-volume cervical tumors or ≥85 Gy for larger-volume cervical tumors. For very small tumors (medically inoperable IA1 or IA2) EQD2 D90 doses of 75–80 Gy may be considered. Grossly involved unresected nodes may be evaluated for boosting with an additional 10 to 15 Gy of highly conformal (and reduced-volume) EBRT. When using image guidance for EBRT, care must be taken to exclude or severely limit the volume of normal tissue included in the high-dose region(s) ([see Discussion](#)).

Posthysterectomy Adjuvant Radiation Therapy^a

- Following primary hysterectomy, the presence of one or more pathologic risk factors may warrant the use of adjuvant radiotherapy. At a minimum, the following should be covered: upper 3 to 4 cm of the vaginal cuff, the parametria, and immediately adjacent nodal basins (such as the external and internal iliac, obturator, and presacral nodes). For documented nodal metastasis, the superior border of the radiation field should be appropriately increased (as previously described). A dose of 45 to 50 Gy in standard fractionation with IMRT is generally recommended.⁵ Grossly involved unresected nodes may be evaluated for boosting with an additional 10 to 20 Gy of highly conformal (and reduced-volume) EBRT. With higher doses, especially of EBRT, care must be taken to exclude or severely limit the volume of normal tissue included in the high-dose region(s) ([see Discussion](#)).
- Consider Vaginal cuff brachytherapy for positive or close vaginal margins.

Intraoperative Radiation Therapy

- IORT is a specialized technique that delivers a single, highly focused dose of radiation to an at-risk tumor bed or isolated unresectable residual disease during an open surgical procedure.⁶ It is particularly useful in patients with recurrent disease within a previously radiated volume. During IORT, overlying normal tissue (such as bowel or other viscera) can be manually displaced from the region at risk. IORT is typically delivered with electrons, brachytherapy, or miniaturized x-ray sources using preformed applicators of variable sizes matched to the surgically defined region at risk, which further constrains the area and depth of radiation exposure to avoid surrounding normal structures.

Re-irradiation

- Techniques for re-irradiation may include IORT, intracavitary or interstitial brachytherapy, SBRT, IMRT, or proton therapy. Such cases are highly customized and depend on the target, proximity to critical organs, previous RT dose, extent of overlap, and time intervals since prior RT. The appropriate dose for each case needs to be individualized.

^a [Normal Tissue Dose Constraints \(CERV-D 6 of 9\)](#).**Note:** All recommendations are category 2A unless otherwise indicated.**Clinical Trials:** NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.

PRINCIPLES OF RADIATION THERAPY¹

General Treatment Information—Continued

Treatment Information - Brachytherapy^a

- Brachytherapy is a critical component of definitive RT for patients with primary cervical cancer. This is usually performed using an intracavitary approach, with an intrauterine tandem and vaginal colpostats. Depending on the patient and tumor anatomy, the vaginal component of brachytherapy in patients with an intact cervix may be delivered using ovoids, ring, or cylinder brachytherapy (combined with the intrauterine tandem). For more advanced disease, or without sufficient regression, interstitial needles may allow increased dose to the target, while minimizing dose to the normal tissues. MRI immediately preceding or during brachytherapy may be helpful in delineating residual tumor geometry. When combined with EBRT, brachytherapy is often initiated towards the latter part of treatment, when sufficient primary tumor regression has been noted to permit satisfactory brachytherapy apparatus geometry. In highly selected, very early disease (ie, stage IA2), brachytherapy alone (without EBRT) may be an option.
- In rare cases, patients whose anatomy or tumor geometry renders intracavitary brachytherapy infeasible may be best treated using an interstitial approach; however, such interstitial brachytherapy should only be performed by individuals and at institutions with appropriate experience and expertise, and early referral for timely use of their expertise is critical.
- In selected patients who receive post-hysterectomy (especially those with positive or close vaginal mucosal surgical margins), vaginal cylinder brachytherapy may be used as a boost to EBRT. The prescription is typically to the vaginal surface or at 5 mm below the surface. Typical fractionation schemes include 5.5 Gy X 2 fractions dosed at 5 mm or 6 Gy X 3 fractions dosed at the vaginal surface.
- SBRT is not considered an appropriate routine alternative to brachytherapy.
- Consider the use of intraprocedural imaging when placing brachytherapy applicators for intact cervical cancer.

**PRINCIPLES OF RADIATION THERAPY¹****Dosing Prescription Regimen - Brachytherapy^a**

- **Point A**, representing a paracervical reference point, has been the most widely used dosing parameter to date. However, limitations of the point A dosing system include the fact that it does not take into account the 3D shape of tumors, nor individual tumor to normal tissue structure correlations. Traditionally point A doses were based on widely validated dose fractionation for brachytherapy with LDR. The dose at point A assumes an LDR delivery of 40–70 cGy/h. The traditional LDR point A prescription dose was 70–80 Gy. Typical point A prescription doses are 5.5 Gy X 5 fractions for early disease and 6 Gy X 5 fractions for large tumors or those demonstrating a poor response. Another reasonable choice that has been well-studied in European trials for intracavity dosing to the high-risk CTV (HR-CTV) is 28 Gy in 4 fractions.
- Interstitial brachytherapy is an advanced technique where multiple needles/catheters are inserted in the gross disease/target. Interstitial brachytherapy may be preferred to maximize dose to the target and minimize dose to the OARs for cases where intracavitary brachytherapy is not possible, or anatomy favors interstitial. 3D treatment planning allows for volumetric delineation of targets and OARs on CT and/or MRI with DVHs. Dose and fractionation depend on prior RT dose, target volume, and OAR doses.
- There is evidence that image-guided brachytherapy improves outcomes and decreases toxicity.⁷ MRI gives the best soft tissue imaging for residual disease and while it is best to have an MRI with the instruments in place, an MRI prior to brachytherapy can help guide therapy. In the absence of MRI, CT can be used but is inferior for determination of residual disease and contouring is less accurate. The goals of care would include an equivalent dose at 2 Gy (EQD2) to the HR-CTV with a D90 of 80–85 Gy; however, with large disease or poor response dose goals should be HR-CTV D90 ≥87 Gy. Normal tissues should be limited according to published guidelines with 2-cc rectal dose ≤65–75 Gy, sigmoid 2-cc dose ≤70–75 Gy, and 2-cc bladder dose ≤80–90 Gy. If those parameters cannot be achieved, supplemental dosing with interstitial needles should be considered.⁸⁻¹¹
- For brachytherapy in combination with EBRT, the external dose is delivered at 1.8–2.0 Gy per daily fraction. Clinicians using high dose-rate (HDR) brachytherapy use dosing based on the linear-quadratic model equation to convert nominal HDR dose to a biologically equivalent LDR dose (<http://www.americanbrachytherapy.org/guidelines/>). The HDR fractionation schedule of 5 fractions delivering 6 Gy nominal dose results in a nominal HDR dose of 30 Gy in 5 fractions, which is generally accepted to be the equivalent to 40 Gy to point A (tumor surrogate dose) using LDR brachytherapy.

**SEDLIS CRITERIA FOR EXTERNAL PELVIC RADIATION AFTER RADICAL HYSTERECTOMY
IN NODE-NEGATIVE, MARGIN-NEGATIVE, PARAMETRIA-NEGATIVE CASES^{a-c,1,2}**

LVSI	Stromal Invasion	Tumor Size (cm) (determined by clinical palpation)
+	Deep 1/3	Any
+	Middle 1/3	≥2
+	Superficial 1/3	≥5
-	Middle or deep 1/3	≥4

LVSI: Lymphovascular space invasionFootnotes

^a Modified with permission from Sedlis A, Bundy BN, Rotman MZ, et al. A randomized trial of pelvic radiation therapy versus no further therapy in selected patients with stage IB carcinoma of the cervix after radical hysterectomy and pelvic lymphadenectomy: a gynecologic oncology study group. *Gynecol Oncol* 1999;73:177-183.

^b Risk factors may not be limited to the Sedlis criteria.

^c Sedlis criteria were developed primarily for squamous cell carcinoma. Histology-specific nomograms for squamous and adenocarcinoma lesions may provide a more contemporary tool to model the risk of recurrence and base adjuvant recommendations. Depth of invasion is an important risk factor of recurrence for squamous lesions. Tumor size is an important risk factor for cervical adenocarcinoma, and this risk becomes more pronounced with the presence of LVSI.³

PRINCIPLES OF GYNECOLOGIC SURVIVORSHIP

Physical Effects

- Gynecologic cancer treatment typically involves surgery, chemotherapy, hormone therapy, radiation therapy, and/or immunotherapy. These treatments cause acute, short-term, and long-term toxicities.
 - Surgical approaches may be extensive and pose risks such as adhesion formation, which may cause pain and may contribute to small bowel obstruction, urinary or gastrointestinal complications (eg, incontinence, diarrhea), pelvic floor dysfunction (manifested by a variety of urinary, bowel, and/or sexual effects), and lymphedema.
 - Chemotherapy agents vary, though commonly used regimens may pose a significant risk of neurotoxicity, cardiac toxicity, development of hematologic cancers, and cognitive dysfunction.
 - Long-term estrogen deprivation may cause symptoms such as hot flashes, vaginal dryness, and bone loss.
 - Radiation therapy may cause long-term complications (eg, fibrosis, vulvovaginal atrophy) and may predispose patients to secondary cancers of the subcutaneous tissue, and/or underlying organs that are proximal to the radiation field.
 - Prior pelvic RT may contribute to bone loss and increase the risk of pelvic fractures. Consider bone density testing and prophylactic use of bisphosphonates, particularly in patients with osteoporosis.
- Immunotherapy use is emerging, and to date, long-term effects of these treatments are unknown.

Psychosocial Effects

- Psychosocial effects after cancer may be psychological (eg, depression, anxiety, fear of recurrence, altered body image), financial (eg, return to work, insurance concerns), and/or interpersonal (eg, relationships, sexuality, intimacy) in nature.

Clinical Approach

- All gynecologic cancer survivors should receive regular general medical care that focuses on managing chronic disease, monitoring cardiovascular risk factors, providing recommended vaccinations, and encouraging adoption of a healthy lifestyle.
- In order to assess the late and long-term effects of gynecologic cancers, clinicians should comprehensively document the patient's history, conduct a thorough physical examination, and provide any necessary imaging and/or laboratory testing. All patients, whether sexually active or not, should be asked about genitourinary symptoms, including vulvovaginal dryness. Referral to appropriate specialty providers (eg, physical therapy, pelvic floor therapy, sexual therapy, psychotherapy) is recommended. As most treatments for gynecologic cancers will cause sexual dysfunction, early menopause, and infertility, special attention to the resultant medical and psychosocial implications is needed.
- Post-radiation use of vaginal dilators and moisturizers is recommended.
- For treatment-related menopause, hormone therapy should be considered.
- Communication and coordination with all clinicians involved in the care of survivors, including primary care clinicians, is critical. Providing cancer survivors with a summary of their treatment and recommendations for follow-up is recommended.

Additional Guidance

- [NCCN Guidelines for Distress Management](#)
- [NCCN Guidelines for Smoking Cessation](#)

Note: All recommendations are category 2A unless otherwise indicated.

Clinical Trials: NCCN believes that the best management of any patient with cancer is in a clinical trial. Participation in clinical trials is especially encouraged.

**Table 1: International Federation of Gynecology and Obstetrics (FIGO) Surgical Staging of Cancer of the Cervix Uteri (2018)**

Stage	Description
I	The carcinoma is strictly confined to the cervix (extension to the corpus should be disregarded).
IA	Invasive carcinoma that can be diagnosed only by microscopy with maximum depth of invasion ≤ 5 mm ^a
IA1	Measured stromal invasion ≤ 3 mm in depth
IA2	Measured stromal invasion >3 mm and ≤ 5 mm in depth
IB	Invasive carcinoma with measured deepest invasion >5 mm (greater than stage IA); lesion limited to the cervix uteri with size measured by maximum tumor diameter ^b
IB1	Invasive carcinoma >5 mm depth of stromal invasion and ≤ 2 cm in greatest dimension
IB2	Invasive carcinoma >2 cm and ≤ 4 cm in greatest dimension
IB3	Invasive carcinoma >4 cm in greatest dimension
II	The cervical carcinoma invades beyond the uterus, but has not extended onto the lower third of the vagina or to the pelvic wall
IIA	Involvement limited to the upper two-thirds of the vagina without parametrial invasion
IIA1	IIA1 Invasive carcinoma ≤ 4 cm in greatest dimension
IIA2	Invasive carcinoma >4 cm in greatest dimension
IIB	With parametrial invasion but not up to the pelvic wall
III	The carcinoma involves the lower third of the vagina and/or extends to the pelvic wall and/or causes hydronephrosis or non-functioning kidney and/or involves pelvic and/or paraaortic lymph nodes
IIIA	Carcinoma involves lower third of the vagina, with no extension to the pelvic wall
IIIB	Extension to the pelvic wall and/or hydronephrosis or non-functioning kidney (unless known to be due to another cause)
IIIC	Involvement of pelvic and/or paraaortic lymph nodes (including micrometastases), ^c irrespective of tumor size and extent (with r and p notations).
IIIC1	Pelvic lymph node metastasis only
IIIC2	Paraortic lymph node metastasis
IV	The carcinoma has extended beyond the true pelvis or has involved (biopsy proven) the mucosa of the bladder or rectum. A bullous edema, as such, does not permit a case to be allotted to stage IV
IVA	Spread of the growth to adjacent organs
IVB	Spread to distant organs

^a Imaging and pathology can be used, when available, to supplement clinical findings with respect to tumor size and extent, in all stages. Pathological findings supersede imaging and clinical findings.

^b The involvement of vascular/lymphatic spaces should not change the staging. The lateral extent of the lesion is no longer considered.

^c Isolated tumor cells do not change the stage but their presence should be recorded.

^d Adding notation of r (imaging) and p (pathology) to indicate the findings that are used to allocate the case to Stage IIIC. Example: If imaging indicates pelvic lymph node metastasis, the stage allocation would be Stage IIIC1r, and if confirmed by pathologic findings, it would be Stage IIIC1p. The type of imaging modality or pathology technique used should always be documented.

NCCN Categories of Evidence and Consensus	
Category 1	Based upon high-level evidence, there is uniform NCCN consensus that the intervention is appropriate.
Category 2A	Based upon lower-level evidence, there is uniform NCCN consensus that the intervention is appropriate.
Category 2B	Based upon lower-level evidence, there is NCCN consensus that the intervention is appropriate.
Category 3	Based upon any level of evidence, there is major NCCN disagreement that the intervention is appropriate.

All recommendations are category 2A unless otherwise indicated.

NCCN Categories of Preference	
Preferred intervention	Interventions that are based on superior efficacy, safety, and evidence; and, when appropriate, affordability.
Other recommended intervention	Other interventions that may be somewhat less efficacious, more toxic, or based on less mature data; or significantly less affordable for similar outcomes.
Useful in certain circumstances	Other interventions that may be used for selected patient populations (defined with recommendation).

All recommendations are considered appropriate.

Overview

An estimated 13,820 new cases of carcinoma of the uterine cervix (ie, cervical cancer) will be diagnosed in the United States in 2024, and 4360 people are estimated to die of the disease.¹ Although cervical cancer rates are decreasing in the United States following the introduction of screening, incidence remains high among Hispanic/Latino, Black, and Asian populations.²⁻⁵ The incidence rates of cervical squamous cell carcinoma are highest in Black and Hispanic individuals assigned female at birth (AFAB), while incidence rates of cervical adenocarcinoma are highest among Hispanic and white AFAB individuals.^{6,7} However, cervical cancer is a major world health problem for AFAB individuals. Globally in 2020, there were an estimated 604,127 cervical cancer cases and 341,831 deaths associated with cervical cancer.⁸ It is the fourth most common cancer in AFAB individuals worldwide with 85% of cases occurring in developing countries—where cervical cancer is a leading cause of cancer death in AFAB individuals.^{1,8-10} It is the most diagnosed cancer in 23 countries and the leading cause of cancer death in 36 countries.¹¹

Squamous cell carcinoma (SCC), adenocarcinoma (AC), adenosquamous carcinoma (ASC) are the three common histologies of cervical cancer. SCC accounts for approximately 80% and AC accounts for approximately 20% of all cervical cancers. In developed countries, the substantial decline in incidence and mortality of SCC of the cervix is presumed to be the result of effective screening and higher human papillomavirus (HPV)-vaccination coverage, although racial, ethnic, and geographic disparities exist.^{2,3,9-12}

However, AC/ASC of the cervix have increased over the past 3 decades, probably because cervical cytologic screening methods are less effective for AC/ASC as the lesions are located deeper than the ectocervix.¹³⁻¹⁷ The ASC subtype is rare and accounts for approximately 5% to 6% of all cervical carcinomas. Presently, there is no difference in treatment between

SCC and AC/ASC cervical cancer subtypes although the clinical features and prognosis of disease varies considerably between these subtypes.

Persistent HPV infection is the most important factor in the development of cervical cancer.^{18,19} The incidence of cervical cancer appears to be related to the prevalence of HPV in the population. In countries with a high incidence of cervical cancer, the prevalence of chronic HPV is approximately 10% to 20%, whereas the prevalence in low-incidence countries is 5% to 10%.¹³ Screening methods using HPV testing may increase detection of adenocarcinoma. Immunization against HPV prevents infection with the types of HPV against which the vaccine is designed and, thus, is expected to prevent specific HPV cancer.²⁰⁻²⁷ HPV vaccines may also decrease the incidence of both squamous cell carcinoma and adenocarcinoma.^{15,28} Although a majority of studies report that most cervical cancers are caused by HPV, around 5% of the tumors are reported as HPV-independent tumors.^{29,30} Other epidemiologic risk factors associated with cervical cancer are a history of smoking, parity, oral contraceptive use, early age of onset of coitus, larger number of sexual partners, history of sexually transmitted disease, certain autoimmune diseases, and chronic immunosuppression.³¹⁻³³ Smoking cessation should be advised in current smokers, and former smokers should continue to avoid smoking (see the [NCCN Guidelines for Smoking Cessation](#) and <http://smokefree.gov/>).

In 2020, the World Health Organization (WHO) updated the Female Genital Tumors classification of cervical cancer by subdividing the cervical cancer lesions into HPV-associated and HPV-independent tumors based on the new pathological findings.³⁴ Among these, the HPV-associated SCC is the most prevalent subtype, with very rare occurrences of the HPV-independent SCC. The HPV-independent AC has a less favorable prognosis as compared to the HPV-associated tumors. The NCCN Cervical Cancer Guidelines Panel acknowledges that while the prior

versions of the WHO classification discussed these tumors based on morphologic features, the integration of the immunohistochemical and molecular profiles has led to a better classification system that is now adapted in the 2020 WHO Classification of Female Genital Tumors for cervical cancer.³⁴ Regardless of cancer subtype and HPV infection status, primary treatment with curative intent for patients with cervical cancer typically consists of surgery, chemoradiation, or a combination of these treatments; options vary by cancer stage. By definition, the NCCN Guidelines cannot incorporate all possible clinical variations and are not intended to replace good clinical judgment or individualization of treatments. “Many exceptions to the rule” were discussed among the members of the Cervical Cancer Panel during the process of developing these guidelines.

Guidelines Update Methodology

The complete details of the Development and Update of the NCCN Guidelines are available at www.NCCN.org.

Literature Search Criteria

Prior to the update of this version of the NCCN Clinical Practice Guidelines in Oncology (NCCN Guidelines®) for Cervical Cancer, an electronic search of the PubMed database was performed to obtain key literature in cervical cancer published since the previous Guidelines update, using the following search terms: cervical cancer or cervical carcinoma or carcinoma of the cervix. The PubMed database was chosen as it remains the most widely used resource for medical literature and indexes only peer-reviewed biomedical literature.

The search results were narrowed by selecting studies in humans published in English. Results were confined to the following article types: Clinical Trial, Phase II; Clinical Trial, Phase III; Clinical Trial, Phase IV;

Guideline; Randomized Controlled Trial; Meta-Analysis; Systematic Reviews; and Validation Studies.

The data from key PubMed articles as well as articles from additional sources deemed as relevant to these Guidelines as discussed by the Panel during the Guidelines update have been included in this version of the Discussion section. Recommendations for which high-level evidence is lacking are based on the Panel’s review of lower-level evidence and expert opinion.

Sensitive/Inclusive Language Usage

NCCN Guidelines strive to use language that advances the goals of equity, inclusion, and representation. NCCN Guidelines endeavor to use language that is person-first; not stigmatizing; anti-racist, anti-classist, anti-misogynist, anti-ageist, anti-ableist, and anti-weight-biased; and inclusive of individuals of all sexual orientations and gender identities. NCCN Guidelines incorporate non-gendered language, instead focusing on organ-specific recommendations. This language is both more accurate and more inclusive and can help fully address the needs of individuals of all sexual orientations and gender identities. NCCN Guidelines will continue to use the terms men, women, female, and male when citing statistics, recommendations, or data from organizations or sources that do not use inclusive terms. Most studies do not report how sex and gender data are collected and use these terms interchangeably or inconsistently. If sources do not differentiate gender from sex assigned at birth or organs present, the information is presumed to predominantly represent cisgender individuals. NCCN encourages researchers to collect more specific data in future studies and organizations to use more inclusive and accurate language in their future analyses.

Diagnosis and Workup

These NCCN Guidelines discuss squamous cell carcinoma, adenosquamous carcinoma and adenocarcinoma of the cervix. The primary workup for small cell neuroendocrine carcinoma is discussed in *Small Cell Neuroendocrine Carcinoma of the Cervix (NECC)* section. Glassy-cell carcinomas, sarcomas, and other histologic types are not within the scope of these Guidelines.

The earliest stages of cervical carcinoma may be asymptomatic or associated with a watery vaginal discharge and postcoital bleeding or intermittent spotting. Often these early symptoms are not recognized by the patient. Because of the accessibility of the uterine cervix, cervical cytology or Papanicolaou (Pap) smears and cervical biopsies can usually result in an accurate diagnosis. Cone biopsy (ie, conization) is recommended if the cervical biopsy is inadequate to define invasiveness or if accurate assessment of microinvasive disease is required. The shape and depth of the cone biopsy may be tailored to the size, type, and location of the neoplastic lesion. For example, if there is concern for invasive adenocarcinoma versus adenocarcinoma in situ in the cervical canal, the cone biopsy would be designed as a narrow, long cone extending to the internal os in order not to miss possible invasion in the endocervical canal. Length of the cold cone of at least 10 mm is preferred and can be increased to 18 to 20 mm in patients who have completed childbearing.³⁵ However, cervical cytologic screening methods are less useful for diagnosing adenocarcinoma, because adenocarcinoma in situ affects areas of the cervix that are harder to sample (ie, endocervical canal).^{16,36} The College of American Pathologists (CAP) protocol for cervical carcinoma is a useful guide

(https://documents.cap.org/protocols/Cervix_5.0.1.3.REL_CAPCP.pdf).

This CAP protocol was revised in March 2022 and reflects recent updates in AJCC staging (ie, AJCC Cancer Staging Manual, 9th edition) and International Federation of Gynecology and Obstetrics (FIGO) cancer

report 2018.³⁷ All staging guidelines are based on 2018 FIGO staging, unless otherwise noted.

Workup for these patients with suspicious symptoms includes history and physical examination, complete blood count (CBC, including platelets), and liver and renal function tests. Recommended radiologic imaging includes pelvic MRI, neck/chest/abdomen/pelvis/groin FDG-PET/CT, chest radiograph, CT, or combined PET/CT, and MRI as indicated (eg, to rule out disease high in the endocervix). For detailed imaging recommendations by stage and planned treatment approach, see *Principles of Imaging* in the NCCN Guidelines® for Cervical Cancer. Smoking cessation and counseling, as well as HIV testing (especially in younger patients), are recommended. Cystoscopy and proctoscopy are only recommended if bladder or rectal extension is suspected (ie, for ≥ stage IB3). Options for fertility sparing should be considered, or referral to reproductive endocrinology and infertility (REI) specialist.

Principles of Staging and Surgery

Clinical Staging

The Panel has updated the Guidelines for Cervical Cancer according to the revised 2018 FIGO staging system.^{38,39} The definitions for lesion size and microinvasion for stage I have been revised. For stage IA, the lateral extent of the lesion no longer affects staging. Stage IB is now divided into 3 subgroups as follows: IB1 includes invasive carcinomas >5 mm and ≤2 cm in greatest diameter; IB2 includes tumors >2 cm and ≤4 cm; and IB3 designates tumors >4 cm. Consideration of nodal metastasis has also been revised; radiology (r) or pathology (p) findings may be used to assess retroperitoneal nodal involvement and are indicated for stage IIIC. Nodal involvement is now designated as stage IIIC, which is subdivided into IIIC1 for pelvic nodes only, and IIIC2 for para-aortic node involvement. Importantly, lymphovascular space invasion (LVSI) does not alter the FIGO classification. FIGO did not include LVSI because pathologists do

not always agree on whether LVSI is present in tissue samples. Some Panel members believe that patients with stage IA1 who have extensive LVSI should be treated using stage IB1 guidelines.³⁸ The staging and treatment recommendations by stage have been revised according to FIGO 2018 in the algorithm, and some of the data cited within this section utilized the previous 2009 FIGO staging system.^{40,41}

Surgical Staging

Pathologic Assessment

Surgicopathologic factors may be used to guide the extent of surgical staging and treatment decisions. Findings from pathologic assessment of the surgical specimen should be carefully documented according to CAP protocol for cervical carcinoma. Important elements of primary tumor evaluation include tumor site; primary tumor volume (in multiple dimensions); histologic type and grade; stromal invasion including pattern of invasion; surgical margin status; and the presence of LVSI. When evaluating patterns of stromal invasion in endocervical adenocarcinoma, the Silva system is utilized, which subdivides these tumors into three categories (see *Principles of Pathology* section).⁴² When evaluating histologic type, according to the 2018 International Endocervical Adenocarcinoma Criteria and Classification (IECC),⁴³ morphologic features (luminal mitotic figures and apoptosis) can be used to distinguish between HPV-associated endocervical adenocarcinomas and HPV-independent adenocarcinomas. Tumors can be further subtyped based on morphologic features. When resected, the number of lymph nodes with isolated tumor cells, micrometastases, and macrometastases should be recorded. When sentinel lymph node (SLN) mapping is performed, SLNs should undergo ultra staging for detection of low-volume metastasis; non-sentinel nodes do not require ultra staging. Other important factors include tumor involvement of tissues/organs such as the parametrium, vaginal cuff, fallopian tubes, ovaries, peritoneum, omentum, and others.

Uterus-11 was a prospective international multicenter study aimed to evaluate the impact of pre-treatment surgical staging, including removal of bulky lymph nodes, on disease-free survival in patients with locally advanced cervical cancer. A total of 255 patients (surgical arm, n = 130; clinical arm, n = 125) with locally advanced cervical cancer were randomized 1:1 to surgical staging (experimental arm) or clinical staging (control arm) followed by primary platinum-based chemoradiation. After a median follow-up of 90 months (range, 1–123) in both arms, there was no difference in DFS (disease-free survival) between the groups ($P = .084$). The study did not show a difference in DFS between surgical and clinical staging in patients with locally advanced cervical cancer.⁴⁴

Conservative/Fertility-Sparing Approaches

Fertility-sparing approaches may be considered in highly selected patients who have been thoroughly counseled regarding disease risk as well as prenatal and perinatal issues.⁴⁵ Consultation with REI experts are suggested.

Microinvasive disease (FIGO stage IA1 with no LVSI) is associated with an extremely low incidence of lymphatic metastasis,⁴⁶⁻⁴⁹ and conservative treatment with conization is an option for individuals with no evidence of LVSI. The goal of conization is *en bloc* removal of the ectocervix and endocervical canal; the Panel recommends cold knife conization as the preferred approach to conization. However, loop electrosurgical excision procedure (LEEP) is acceptable if adequate margins, proper orientation, and a non-fragmented specimen without electrosurgical artifact can be obtained.⁵⁰⁻⁵⁵ Endocervical curettage should be added as clinically indicated except in pregnancy.

Based on ConCerv trial, select patients with stage IA2 and IB1, especially for those with tumors of less than 2 cm in diameter and who meet all the

conservative surgery criteria with no evidence of LVSI, may be eligible for conservative surgery with pelvic lymphadenectomy or SLN mapping.^{41,56,57}

The objective of the ConCerv Trial was to prospectively evaluate the feasibility of conservative surgery in women with early-stage, low-risk cervical cancer. The eligibility criteria included: (1) FIGO 2009 stage IA2–IB1 cervical carcinoma; (2) squamous cell (any grade) or adenocarcinoma (grade 1 or 2 only) histology; (3) tumor size <2 cm; (4) no LVSI; (5) depth of invasion <10 mm; (6) negative imaging for metastatic disease; and (7) negative conization margins.

One hundred evaluable patients were enrolled, and the surgery included conization followed by lymph node assessment in 44 women, conization followed by simple hysterectomy with lymph node assessment in 40 women, and inadvertent simple hysterectomy followed by lymphadenectomy in 16 women. Positive lymph nodes were noted in 5 patients. Residual disease in the post-conization hysterectomy specimen was noted in 1/40 patients—that is, an immediate failure rate of 2.5%. The study concluded that select patients with early-stage, low-risk cervical carcinoma may be offered conservative surgery, and the Panel updated the treatment options for patients with early stage, low risk, stage IA2 and IB1 cancer.

Radical trachelectomy may offer a reasonable fertility-sparing treatment option for patients with stage IA1–IA2 (with LVSI), IB1 (not meeting conservative surgery), and select IB2 cervical cancer with lesions that are 2 to 4 cm.⁵⁸⁻⁶⁰ In a radical trachelectomy, the cervix, vaginal margins, and supporting ligaments are removed while leaving the main body and fundus of the uterus intact.⁶¹ Laparoscopic pelvic lymphadenectomy accompanies the procedure and can be performed with or without SLN mapping (see *Lymph Node Mapping and Dissection* below). Para-aortic lymphadenectomy can be added for stage 1B1 and select patients with IB2 cervical cancer.⁶²

Due to their aggressive nature, tumors of small cell neuroendocrine histology are considered inappropriate for radical trachelectomy.⁶³ Trachelectomy is also inappropriate for treating gastric type cervical adenocarcinoma and adenoma malignum (minimal deviation adenocarcinoma) due to their diagnostic challenges and potentially aggressive nature.⁶⁴

Vaginal radical trachelectomy (VRT) may be used for carefully selected patients with lesions of 2 cm diameter or less.⁶⁵⁻⁶⁷ Abdominal radical trachelectomy (ART) provides a broader resection of the parametria^{58,67} than the vaginal approach and is commonly used in stage IB1 lesions. Multiple case series have evaluated safety and outcomes with vaginal versus abdominal approaches to radical trachelectomy,^{65,68-70} including systematic reviews on VRT⁷¹ and ART.⁷² A limited number of studies have specifically examined this approach in patients with tumors between 2 cm and 4 cm in diameter and reported safe oncologic outcomes; however, as expected, more patients in this subgroup will require adjuvant therapy, which may reduce fertility.⁷³⁻⁷⁵

Studies that examined pregnancy in patients who underwent radical trachelectomy have provided differing success rates. One case series of 125 patients with cervical cancer who underwent VRT reported 106 pregnancies among 58 females.⁶⁶ In a systematic review of 413 females who underwent ART, 113 of those attempted pregnancy and 67 (59%) successfully conceived.⁶⁹ However, miscarriage and pre-term labor rates were elevated among those who underwent radical trachelectomy.^{66,76-78}

Non-Fertility-Sparing Approaches

The Querleu and Morrow surgical classification system^{79,80} describes the degree of resection and nerve preservation for radical hysterectomy in three-dimensional planes and updates the previously used Piver-Rutledge classifications.⁸¹ Approaches to hysterectomy include simple/extrafascial

NCCN Guidelines Version 3.2024

Cervical Cancer

hysterectomy (Type A), modified radical hysterectomy (Type B), and radical hysterectomy (Type C).^{82,83}

For patients with IA1 disease, cone excision, simple/extrafascial hysterectomy, and modified radical hysterectomy are options. Radical hysterectomy with bilateral pelvic lymphadenectomy (with or without SLN mapping) is the preferred treatment approach for patients with FIGO stage IA2, IB1, IB2, and IIA1 cervical cancers. Radical hysterectomy is preferred over simple hysterectomy due to its wider paracervix margin of resection that also includes aspects of the cardinal and uterosacral ligaments, upper vagina, pelvic nodes, and at times, para-aortic nodes. In the United States, definitive chemoradiation is typically preferred over radical surgery for select patients with FIGO IB3 lesions and the vast majority of FIGO stage IIA2 or greater cervical cancers. Abroad, select FIGO stage IB3–IIB cases may be treated with radical hysterectomy or neoadjuvant chemotherapy followed by radical hysterectomy.

For recurrent or persistent cervical cancers that are confined to the central pelvis (ie, no distant metastasis), pelvic exenteration may be a potentially curative surgical option.^{84,85} Discussion of the various approaches to pelvic exenteration are offered by Chi and colleagues,⁸² and in the Gynecologic Oncology Group (GOG) Surgical Manual.⁸³

Lymph Node Mapping and Dissection

Sentinel Lymph Node Mapping

Based on cumulative published data, SLN biopsy may be useful for decreasing the need for pelvic lymphadenectomy in patients with early-stage cervical cancer and to detect low-volume metastasis.^{86,87}

Prospective studies generally support the feasibility of SLN detection in patients with early-stage cervical cancer and suggest that extensive pelvic lymphadenectomy may be safely avoided in a significant proportion of early-stage cases.⁸⁶⁻⁹⁷

Meta-analyses of pooled data from SLN mapping studies have generated SLN detection rates of 89% to 92% and sensitivity of 89% to 90%.^{98,99} Factors determined to be important for detection included laparoscopy, dual blue dye/radiocolloid tracer approaches, and pathologic assessment using immunohistochemistry. However, based on a meta-analysis, indocyanine green (ICG) tracer appears to provide similar overall and bilateral detection rates to the standard dual blue dye/technetium-99 approach.¹⁰⁰ The randomized phase III FILM trial demonstrated that ICG tracer identified more SLNs (overall and bilateral) than blue dye.¹⁰¹

Study data also highlight limited sensitivity of this approach and potential to miss SLN micrometastases and isolated tumor cells using intraoperative assessment (ie, frozen section or imprint cytology).^{89,93,95} The sensitivity of this approach appears to be better in patients with tumors equal to or less than 2 cm in diameter.^{86,88,90,102} Ultra staging of detected SLNs has been shown to provide enhanced detection of micrometastases.^{91,92}

The SENTICOL longitudinal study demonstrated the utility of SLN mapping to uncover unusual lymph drainage patterns.^{90,103} It also highlighted limited agreement between lymphoscintigraphy and intraoperative SLN mapping.¹⁰³ Additionally, this study revealed that bilateral SLN detection and biopsy provided a more reliable assessment of sentinel nodal metastases and led to fewer false negatives than unilateral SLN biopsy.⁸⁷

The SENTICOL-2 study also demonstrates the benefits of omitting pelvic lymphadenectomy in terms of decreased lymphatic morbidity. The study showed that lymphatic morbidity was significantly lower in the sentinel node resection alone (SN arm) (31.4%) than in the SN and pelvic lymph node dissection (SN + PLND arm) (51.5%; $P = .0046$), as was the rate of postoperative neurological symptoms (7.8% vs. 20.6%; $P = .01$, respectively).¹⁰⁴ Generally, research supports ipsilateral lymphadenectomy

if no sentinel nodes are detected on a given side of the pelvis as outlined in the SLN mapping algorithm.^{86,87,105}

Based on these collective data, the Panel recommends consideration of SLN mapping algorithm and emphasizes that best detection and mapping results are in tumors of less than 2 cm diameter. Adherence to the SLN mapping algorithm is important; surgeons should perform side-specific nodal dissection in any cases of failed mapping and remove all suspicious or grossly enlarged nodes regardless of SLN mapping.⁸⁶

Para-Aortic Lymph Node Assessment

Studies of the incidence and distribution of lymph node metastases in patients with stage IB to IIB cervical cancers suggest that para-aortic lymph node involvement is closely tied to the presence of pelvic lymph node metastases, larger primary tumor size (>2 cm), and metastasis to the common iliac nodes.^{106,107}

Analysis of outcomes data from 555 patients who participated in GOG trials (GOG 85, GOG 120, and GOG 165) revealed a more positive prognosis for patients who underwent surgical exclusion of para-aortic lymph node involvement versus those who underwent radiographic determination of para-aortic node involvement.¹⁰⁸ One study examined the efficacy of extending the radiation therapy (RT) field to the para-aortic region in patients with para-aortic lymph node involvement, and showed therapeutic benefit especially in patients with small-volume nodal disease.¹⁰⁹

The ongoing PAROLA trial aims to demonstrate if chemoradiation with tailored EBRT based on surgical staging and pathologic examination of the para-aortic lymph node is associated with improved survival compared with patients staged with radiologic staging only and the accrual is estimated to be completed in 2027.¹¹⁰

The Panel recommends para-aortic lymphadenectomy for patients with \geq stage IB1 disease.

Minimally Invasive Surgical Approaches

The standard and historical approach for radical hysterectomy is with an open abdominal approach.

Previous iterations of the Guidelines had indicated that radical hysterectomy could be performed either via open laparotomy or minimally invasive surgery (MIS) laparoscopic approaches, using either conventional or robotic techniques. Data from previous retrospective reviews and prospective observational studies demonstrated oncologic outcomes following conventional laparoscopic radical hysterectomy that were comparable to open abdominal approaches after 3 to 6 years of follow-up.¹¹¹⁻¹¹⁴ Similarly, multicenter retrospective reviews and matched cohort studies showed comparable oncologic outcomes (disease recurrence and survival rates) for open abdominal and robotic radical hysterectomy after 3 to 5 years of follow-up.¹¹⁴⁻¹¹⁷ Additionally, a systematic review and meta-analysis of data from 26 studies found that laparoscopic and robotic radical hysterectomy approaches appeared to provide equivalent intraoperative and short-term postoperative outcomes.¹¹⁸

However, several key contemporary reports have questioned the presumed therapeutic equivalency of open versus MIS approaches. A pivotal prospective randomized trial demonstrated that minimally invasive radical hysterectomy was associated with lower rates of disease-free survival (DFS) and overall survival (OS) than open abdominal radical hysterectomy.¹¹⁹ This phase III LACC trial (NCT00614211) was designed to provide a definitive comparison of outcomes data in patients with early-stage cervical cancer undergoing total abdominal radical hysterectomy (TARH) or total laparoscopic radical hysterectomy/total robotic radical hysterectomy. At closure, 319 patients had received MIS (84% laparoscopy, 16% robotic) and 312 patients underwent TARH.

Ninety-two percent of participants in both surgical arms had stage IB1 disease. MIS was associated with lower rate of DFS than open surgery (3-year DFS, 91.2% vs. 97.1%; HR, 3.74; 95% CI, 1.63–8.58), as well as a decrease in OS (3-year OS, 93.8% vs. 99.0%; hazard ratio [HR], 6.00; 95% CI, 1.77–20.30).¹¹⁹ MIS did not meet predetermined non-inferiority criteria compared with standard-of-care laparotomy ($P = .88$).

Two other epidemiologic studies also demonstrated that minimally invasive radical hysterectomy was associated with shorter OS than open surgery among patients with stage IA2–IB1 cervical cancer.^{120,121} Melamed et al reported on a SEER-based cohort study that compared females with stage IA2 or IB1 cervical cancer who underwent laparotomy ($n = 1236$) or MIS ($n = 1225$).¹²⁰ Four-year mortality was higher among patients undergoing MIS versus laparotomy (9.1% vs. 5.3%; $P = .002$). Relative survival rates were stable prior to the adoption of MIS techniques (2000–2006), but a significant decline was noted in the years following adoption. Margul et al examined National Cancer Database data from 2010 to 2013 to compare outcomes of patients with stage IB1 cervical cancer who underwent radical hysterectomy performed by open abdominal versus MIS approaches.¹²¹ Although MIS was associated with decreased surgical morbidity and costs, patients with tumor sizes ≥ 2 cm who underwent MIS had decreased 5-year survival compared to those undergoing open radical hysterectomy (81.3% vs. 90.8%; $P < .001$).¹²¹

Another systematic review and meta-analysis of 15 high-quality studies comprising 9499 patients¹²² confirmed that minimally invasive radical hysterectomy was associated with shorter overall and DFS among women with operable cervical cancer compared with open surgery. Of 9499 patients who underwent radical hysterectomy, 49% received minimally invasive surgery; of these, 57% received robot-assisted laparoscopy. The pooled hazard of recurrence or death was 71% higher among patients who underwent minimally invasive radical hysterectomy compared with

those who underwent open surgery (HR, 1.71; 95% CI, 1.36–2.15; $P < .001$), and the hazard of death was 56% higher (HR, 1.56; 95% CI, 1.16–2.11; $P = .004$). No association was found between the prevalence of robot-assisted surgery and the magnitude of association between minimally invasive radical hysterectomy and hazard of recurrence or death or all-cause mortality. This study also concluded that among patients undergoing radical hysterectomy for early-stage cervical cancer, MIS was associated with an elevated risk of recurrence and death compared with open surgery.

These findings stand in contradiction to the earlier referenced series that had suggested therapeutic equivalency of MIS compared to open approaches along with the MIS-associated potential advantages of decreased hospital stay and more rapid patient recovery.^{114,115,117,118,123-126}

Given the findings of poorer oncologic outcomes and survival with the MIS techniques compared to open laparotomy, patients should be carefully counseled about the oncologic risks and potential short-term benefits of the different surgical approaches.

Principles of Pathology

Pathologic Assessment

Silva Classification System for HPV-Associated Endocervical Adenocarcinoma

According to the 2018 FIGO criteria^{38,39} pathologists use tumor size and stromal depth of invasion (DOI) during clinicopathological staging of cervical cancer. During clinicopathological assessment, pathologists calculate DOI (in millimeters) starting from the basement membrane of the originating epithelium.¹²⁷ Endocervical glands normally vary in size, shape, and distance of extension into the underlying stroma. Because of this architectural complexity determining the DOI in endocervical adenocarcinoma (EAC) is difficult.^{128,129} Obtaining an accurate DOI

measurement is important, as it directly informs treatment decisions. The FIGO staging system does not consider the extent of LVSI, but clinicians also use this information to inform treatment decisions. For instance, patients with stage IA1 cervical cancer (DOI ≤ 3 mm) whose tumors do not have LVSI may be candidates for fertility-sparing conservative treatment (ie, cone biopsy, trachelectomy), as these patients generally have low risk of metastasis and recurrence. Patients with IA2 cervical cancer (DOI > 3 mm) may also be candidates for these procedures, but also typically undergo lymphadenectomy with or without SLN mapping due to an increased risk of nodal metastases and recurrence compared to patients with stage IA1 cervical cancer without LVSI. Lymphadenectomy and SLN mapping both may increase morbidity. Therefore, more accurate and reproducible methods of staging EAC are needed to avoid the use of unnecessary procedures in patients who may be at minimal risk of nodal metastases, recurrence, and/or death.

The Silva classification system, which considers the extent of LVSI, stromal invasion, and differentiation, has been proposed to stratify patients more accurately with invasive HPV-associated EAC. A 2013 retrospective study published by Diaz De Vivar et al¹³⁰ included patients (n = 352) with stage I–IV usual-type EAC, all of whom previously underwent lymphadenectomy. Pathologists classified their tumor samples into one of three Silva categories: Category A tumors are characterized by no LVSI, well-demarcated glands, and no detachment, which may resemble adenocarcinoma in situ; Category B, some LVSI, focal destructive stromal invasion; Category C, more widespread LVSI, diffuse destructive stromal invasion.

For tumors that had mixed histopathological characteristics, pathologists assigned the highest classification that they observed in the sample. The mean follow-up time was approximately 4.5 years. Patients with category A tumors did not experience any metastases or recurrences during this

time. Of those with category B tumors, 4.4% experienced metastases and 1.2% had a recurrence. Those with category C tumors had a marked increase in the rate of metastases and recurrences (23.8% and 22.1%, respectively). Thus, tumors with pattern A invasion (defined by well-demarcated glands with round contours, an absence of single cells, an absence of desmoplastic stromal response, and no lymphatic vascular invasion) have excellent survival and do not have lymph node metastases or recurrences.

Since 2013, several other groups independently published retrospective studies on use of the Silva classification system. Spaans et al 2018¹³¹ classified tumor samples from 82 patients with stage IB–IIA HPV-associated EAC, all of whom previously underwent radical hysterectomy or trachelectomy. The median follow-up time was approximately 10 years. Patients with category A tumors did not experience any metastases, recurrences, or deaths during this time. Of patients with category B tumors, 17% experienced metastases, 13% had a recurrence, and 10% died. Of patients with category C tumors, 37% experienced metastases, 35% had a recurrence, and 35% died. The authors suggested that category B and C tumors may be associated with a higher incidence of somatic hotspot mutations but noted that this observation should be confirmed in prospective studies.

Stolnicu et al¹³² used the Silva classification system to stratify 341 patients with HPV-associated and non–HPV-associated stage I through IV EAC who previously underwent surgical resection (ie, cone biopsy, trachelectomy, hysterectomy) and lymphadenectomy. Pathologists first classified tumor specimens into HPV-associated and non–HPV-associated EAC according to IECC criteria¹⁷ and then further classified the tumors by Silva criteria. The authors found that the incidence of metastases in HPV-associated EAC was like that observed by Diaz De Vivar et al.¹³⁰ They also reported that 100% of the non–HPV-associated EAC tumors

were classified as category C, and therefore concluded that the utility of the Silva classification system is limited to patients with HPV-associated EAC.¹³² Stolnicu et al, have also proposed a binary Silva classification system that groups patients into low risk (patterns A and B without lymphovascular invasion) and high risk (pattern B with lymphovascular invasion and pattern C) categories.¹³³ FIGO (2019 classification) stage IA–IB1 EACs from 15 international institutions were examined for Silva pattern, presence of LVSI, and other prognostic parameters.

On multivariate analysis, LVSI ($P = .008$) and Silva pattern ($P < .001$) were significant factors when comparing stage IA versus IB1 endocervical adenocarcinomas. Overall survival was significantly associated with lymph node metastasis ($P = .028$); recurrence-free survival was significantly associated with LVSI ($P = .002$) and stage (1B1 vs. 1A) ($P = .002$). Five- and 10-year overall survival and recurrence-free survival rates were similar among Silva pattern A cases and Silva pattern B cases without LVSI ($P = .165$ and $P = .171$, respectively).

Silva pattern and LVSI are important prognostic factors in stage IA1–IB1 endocervical adenocarcinomas and can supplement FIGO staging.

Data from these retrospective studies suggest that the Silva classification system may help stratify patients with invasive, EAC by risk of metastasis, recurrence, and death. Some expert gynecological pathologists are already using the Silva classification system during clinicopathological staging. The system could be particularly helpful for identifying patients who are low risk with stage I disease who may be candidates for conservative, fertility-sparing treatment without compromising short- and long-term patient health outcomes. However, prospective studies are needed to confirm these observations. If data from future prospective studies agree with the data cited above, the Silva classification system could potentially be used in conjunction with, or incorporated into, FIGO/AJCC criteria at the time of diagnostic biopsy. To this end, Roma et

al¹³⁴ proposed that a new three-tier FIGO/AJCC classification system could be created for HPV-associated EAC staging, in which Silva A, B, and C categories would replace DOI measurement. Alternatively, DOI could be revised to specify the depth of destructive invasion, and the Silva classification system could then be used in conjunction.¹³⁴

Sedlis Criteria

The “Sedlis Criteria,” which are intermediate risk factors used to guide adjuvant treatment decisions, include: 1) greater than one-third stromal invasion; 2) capillary lymphatic space involvement; or 3) cervical tumor diameters more than 4 cm.¹³⁵ However, potentially important risk factors for recurrence may not be limited to the Sedlis Criteria. Additional risk factors for consideration include tumor histology (eg, adenocarcinoma component)^{136,137} and close or positive surgical margins.^{138,139}

Sedlis criteria were developed primarily for squamous cell carcinoma. Histology-specific nomograms for squamous and adenocarcinoma lesions may provide a more contemporary tool to model the risk of recurrence and base adjuvant recommendations. In an ancillary analysis of GOG 49, 92, and 14 studies,¹⁴⁰ among 715 patients with SCC and 105 with AC, 20% with SCC and 17% with AC recurred. For SCC, LVSI (HR, 1.58; 95% CI, 1.12–2.22), tumor size (TS ≥ 4 cm: HR, 2.67; CI, 1.67–4.29), and DOI (middle 1/3, HR, 4.31; 95% CI, 1.81–10.26; deep 1/3, HR, 7.05; 95% CI, 2.99–16.64) were associated with recurrence. For AC, only TS ≥ 4 cm, was associated with recurrence (HR, 4.69; 95% CI, 1.25–17.63). For both histologies, there was an interaction effect between TS and LVSI. For those with SCC, DOI was most associated with recurrence (16% risk); for AC, TS conferred a 15% risk with negative LVSI versus a 25% risk with positive LVSI. While for squamous lesions, DOI is an important risk factor of recurrence, for adenocarcinoma, tumor size is an important risk factor of recurrence, and this risk becomes more pronounced with the presence of

LVSI. It is also important to note that the risk factors may not be limited to the Sedlis criteria. These systems remain to be validated for clinical use.

Prognostic and Predictive Biomarkers

Over the years, systemic therapy options for cervical cancer have undergone a paradigm shift with the emergence of biomarkers and the growing number of newer treatment options available with meaningful improvement in survival rates. As the importance of testing for the presence of certain biomarkers in advanced disease is well recognized, the availability of several agents targeting these specific biomarkers have led to improved outcomes in patients. Testing for these biomarkers is critical to guide treatment selection especially for patients with advanced or recurrent disease. While predictive biomarkers indicate how certain patients are likely to respond to treatment, either in terms of efficacy or toxicity and forecasts pharmacodynamic resistance or toxicity and can guide initial treatment decisions by identifying potentially successful drugs and potentially minimizing toxicity, prognostic biomarkers predict the overall survival in certain patients, independent of therapy and can guide treatment decision-making, monitor disease progression, and detect recurrence.^{141,142}

Several biomarker-based immune-oncologic agents have been added to the Guidelines in the management of recurrent/metastatic cervical cancer in recent years (see *Systemic Therapy Recommendations*) and the NCCN Panel recommends comprehensive molecular profiling as determined by a U.S. Food and Drug Administration (FDA)-approved assay, or a validated test performed in a Clinical Laboratory Improvement Amendments (CLIA)-certified laboratory.

PD-L1

The NCCN Panel recommends programmed death-ligand 1 (PD-L1) testing by an FDA-approved assay, or a validated test performed in a CLIA-certified laboratory for patients with recurrent, progressive, or

metastatic disease to help guide better treatment options in first-line, second-line, or subsequent therapy.¹⁴³

The FDA approved pembrolizumab plus chemotherapy, with or without bevacizumab for patients with persistent, recurrent, or metastatic cervical cancer whose tumors express PD-L1 (combined positive score [CPS] ≥ 1) based on Keynote-826 study.¹⁴³ The NCCN Panel also recommends the same as a preferred regimen (Category 1) for first-line therapy for recurrent or metastatic disease.

KEYNOTE-158 is another phase II basket study that evaluates the use of pembrolizumab in multiple cancer types including cervical cancer.¹⁴⁴ The interim results from previously treated patients with advanced cervical cancer demonstrated the durable antitumor activity and manageable safety of pembrolizumab monotherapy. Out of 98 patients treated, 82 (83.7%) had PD-L1-positive tumors (CPS ≥ 1), 77 having previously received one or more lines of chemotherapy for recurrent or metastatic disease. The primary end point, objective response rate (ORR) was 12.2% (95% CI, 6.5%–20.4%), with three complete and nine partial responses. All 12 responses were in patients with PD-L1-positive tumors, for an ORR of 14.6% (95% CI, 7.8%–24.2%); 14.3% (95% CI, 7.4%–24.1%) of these responses were in those who had received one or more lines of chemotherapy for recurrent or metastatic disease. Based on these results, the FDA granted accelerated approval of pembrolizumab for patients with advanced PD-L1-positive cervical cancer who experienced progression during or after chemotherapy. NCCN also recommends pembrolizumab as a preferred regimen for patients who are PD-L1-positive for second-line or subsequent therapy.

Nivolumab, a checkpoint inhibitor, has shown efficacy in patients with recurrent/metastatic cervical cancer who received at least one prior chemotherapy regimen. The Checkmate-358, phase 1/2, single-arm trial evaluated 19 patients with advanced, pretreated, HPV-associated cervical tumors.¹⁴⁵ The ORR was 26.3% (95% CI, 9.1%–51.2%) and

disease control rate was 68.4% (95% CI, 43.4%–87.4%). The 12-month OS rate was 77.5% (95% CI, 50.5%–91.0%). The phase 2 trial (NRG-GY002) showed low anti-tumor activity of nivolumab in 25 patients with pretreated persistent/recurrent cervical cancer; 36% of the patients had stable disease (90% CI, 20.2%–54.4%) as best response with median duration of 5.7 months, and progression-free survival (PFS) and OS at 6 months was 16% and 78.4%, respectively.^{146,147}

Based on these results, in the 1.2023 version of the NCCN Guidelines for Cervical Cancer, the Panel moved nivolumab from preferred, second-line or subsequent therapy options to the “useful in certain circumstances” category for PD-L1–positive tumors and continues to recommend nivolumab in the same category in version 2.2024.

Mismatch Repair /Microsatellite Instability

Tumors with mismatch repair deficiency (dMMR) represent approximately 2% to 4% of all diagnosed cancers and have a unique genetic signature, harboring 10- to 100-times more mutations than mismatch repair–proficient tumors. These dMMR tumors have high microsatellite instability (MSI-H) and harbor 100 to 1000 of somatic mutations that encode potential neoantigens and are likely to be immunogenic. The Keynote-158 trial included patients with non-colorectal MSI-H/dMMR tumors in cohort K and the results demonstrated the clinical benefit of pembrolizumab in patients with previously treated unresectable or metastatic MSI-H/dMMR non-colorectal cancer.¹⁴⁸

Of 233 patients with MSI-H/dMMR advanced non-colorectal cancer who experienced failure with prior therapy who received pembrolizumab, the objective response rate was 34.3% (95% CI, 28.3%–40.8%). Median PFS was 4.1 months (95% CI, 2.4–4.9 months) and median overall survival was 23.5 months (95% CI, 13.5 months – not reached). The NCCN Panel recommends pembrolizumab as a preferred regimen for

MSI-H/dMMR tumors as a second-line or subsequent therapy for recurrent or metastatic disease.

TMB

Tumor mutational burden (TMB), defined as the total number of somatic mutations per coding area of a tumor genome, is a measure of all non-synonymous coding mutations in a tumor exome and highly mutated tumors can produce many neoantigens, some of which might increase T-cell reactivity. High TMB has been demonstrated to be associated with treatment response to Pembrolizumab.

In a prospective analysis of the multi-cohort, open-label, non-randomized phase 2 KEYNOTE-158 study,¹⁴⁹ the association between antitumor activity and tissue-tumor mutational burden (tTMB) in patients who received at least one dose of pembrolizumab were assessed and tTMB-high status identified a subgroup of patients who could have a robust tumor response to pembrolizumab monotherapy. Out of 790 TMB evaluable, treated patients enrolled by at least 26 weeks before data cutoff, 102 (13%) patients were tTMB-high (<10 mutations per megabase) and 688 (87%) patients had non-tTMB–high status. With a median study follow-up of 37.1 months, the objective responses were observed in 30 (29%; 95% CI, 21–39) of 102 patients in the tTMB-high group and 43 (6%; 95% CI; 5–8) of 688 in the non-tTMB–high group. Cervical cancer had the highest proportion of patients with tTMB-high status (21%) and objective responses were observed in 5/16 patients with tTMB-high status and 7/59 patients with non-tTMB–high status within the cervical cohort.

The NCCN Panel recommends TMB testing by an FDA-approved assay, or a validated test performed in a CLIA-certified laboratory and recommends pembrolizumab as a preferred regimen for the treatment of patients with TMB-H [≥ 10 mutations/mega base (mut/Mb)] tumors that have progressed following prior treatment and who have no satisfactory alternative treatment options (second-line or subsequent therapy).

NTRK Gene Fusion

NTRK gene fusions are found in about 1% of all solid tumors. An integrated efficacy and safety analysis of patients with metastatic or locally advanced solid tumors harboring oncogenic *NTRK1*, *NTRK2*, and *NTRK3* gene fusions treated with entrectinib in three ongoing, early-phase trials (ALKA-372-001, STARTRK-1, and STARTRK-2) showed durable and clinically meaningful responses with manageable safety profile.¹⁵⁰ The efficacy-evaluable population comprised of 54 adults with advanced or metastatic *NTRK* fusion-positive solid tumors comprising ten different tumor types and 19 different histologies, including one patient with cervical sarcoma. Out of 54 patients, 31 (57%; 95% CI, 43.2–70.8) patients had an objective response, of which four (7%) were complete responses and 27 (50%) were partial responses. Median duration of response (DoR) was 10 months (95% CI, 7.1 – not estimable [NE]). In a long-term efficacy and safety analysis in 121 patients at median follow-up of 25.8 months, 61% reported complete or partial responses, median DoR was 20 months (95% CI, 10.1–19.9) and median PFS was 13.8 months (95% CI, 10.1–19.9).¹⁵¹

In another primary analysis, the efficacy and safety of larotrectinib was reported in 55 patients enrolled in three clinical studies who had locally advanced or metastatic tumors with *NTRK* gene fusions and had progressed on standard chemotherapy received previously. The three clinical trials included a phase 1 dose-finding study in adults, phase 1–2 dose-finding study in a pediatric population, and a phase 2, single-arm, basket trial.¹⁵² The overall response rate of Larotrectinib in these patients was 75% (95% CI, 61%–85%) with 13% complete response (CR) and 62% partial responses with median DoR and PFS not reached at the time. In a long-term follow-up analysis, out of 153 patients, 121 patients (79%; 95% CI, 72–85) had objective response with 16% having a CR, 63% with partial response, and 12% with a stable disease. The median DoR was 35.2 months (22.8 – NE) and the median PFS was 28.3 months.¹⁵³ Both larotrectinib and entrectinib are FDA-approved for *NTRK*

gene fusion solid tumors for patients who have progressed following treatment or have no satisfactory standard therapy.^{154,155}

HER2

HER2 expression is observed in a wide range of solid tumors and is an established prognostic biomarker for breast, gastric, and colorectal cancers. Cervical cancer has shown *HER2* positivity rate of approximately 2% to 6% in the literature.¹⁵⁶⁻¹⁵⁸ Trastuzumab deruxtecan is an antibody-drug conjugate that contains the humanized anti-*HER2* monoclonal antibody trastuzumab attached to the topoisomerase inhibitor deruxtecan.¹⁵⁹ Another tumor-agnostic study evaluated the durability and clinically meaningful response of trastuzumab deruxtecan across multiple *HER2*-expressing (immunohistochemistry [IHC] 3+ or 2+) advanced solid tumor types in patients who progressed on prior therapy or who have no satisfactory alternative treatment options.

The DESTINY-PanTumor02 is an open-label, multicenter, phase 2 trial that evaluated Trastuzumab deruxtecan (T-DXd) on 267 patients with *HER2*-expressing (IHC 3+ or 2+) locally advanced or metastatic disease after ≥1 systemic treatment or without alternative treatments. The study included 40 patients with cervical cancer with IHC2+ or 3+ expression of *HER2*. Overall, the ORR was 37.1% (n = 99; [95% CI, 31.3–43.2]), the median PFS was 6.9 months (95% CI, 5.6–8.0); and the median OS was 13.4 months (95% CI, 11.9–15.5). In patients with cervical cancer, the confirmed ORR was 50% and for *HER2* IHC3+ cohort, the ORR was 75% and the median OS was 13.6 months.¹⁶⁰ The Panel recommends *HER2* IHC testing (with reflex to *HER2* fluorescence in situ hybridization [FISH] for equivocal IHC) for advanced, metastatic, or recurrent cervical carcinoma. The guideline includes fam-trastuzumab deruxtecan-nxki as category 2A, useful in certain circumstances, second-line/subsequent therapy option for *HER2*-positive tumors (IHC 3+ or 2+).

**RET Gene Fusion**

The rearranged during transfection (*RET*) gene fusions most commonly occur in thyroid and non-small cell lung cancers and are observed in <1% of patients with other solid tumors. The prognosis of disease in this small subset of patients who have progressed on or following prior systemic therapy is poor. Phase 1/2, Libretto-001, multicenter, open-label trial evaluated the efficacy of selpercatinib in patients with *RET*-mutant advanced solid tumors. In an interim analysis of the trial in a tumor-agnostic population, the efficacy and safety of selpercatinib was investigated in 41 patients with *RET* fusion-positive solid tumors (other than non-small cell lung cancer and thyroid cancer) with disease progression on or after previous systemic therapies or who had no satisfactory therapeutic options. The ORR was 44% (95% CI, 28.5–60.3), with median duration of response 24.5 months (95% CI, 9.2 – NE).^{161 162} Selpercatinib received tumor-agnostic approval by the FDA for patients with solid tumors with a *RET* gene fusion that has progressed on or following prior systemic treatment or who have no satisfactory alternative treatment options. The NCCN Panel recommends that *RET* gene fusion testing may be considered for patients with locally advanced or metastatic cervical cancer. The NCCN Panel also recommends selpercatinib as a biomarker-directed second-line/subsequent therapy under useful in certain circumstances category for

HPV Status/p16

Approximately 80% to 90% of cervical carcinomas worldwide is cervical SCC, a squamous epithelial tumor with stromal invasion and/or exophytic invasion and more than 90% of cervical SCCs are HPV-associated, with HR-HPV 16 and 18 being the most common types. HPV-independent cervical SCC is a relatively recently described entity, with 5% to 7% of cervical SCCs reported to be HPV-negative. Adenocarcinomas of the cervix can be HPV-associated (HR-HPV types 18, 16, and 45 most commonly) or HPV-independent. Adenosquamous carcinoma, an

epithelial tumor with squamous and glandular differentiation accounts for approximately 5% to 6% of all cervical carcinomas and the clinical outcomes are like cervical adenocarcinoma.

Utility of p16 IHC and/or molecular HPV typing is recommended for establishing HPV association in SCC. Almost all HPV-associated SCCs show strong and diffuse p16 overexpression in nuclei and cytoplasm by IHC. Determining the HPV status is recommended as HPV-associated EAC have shown better clinical outcomes compared with HPV-independent adenocarcinomas. 95% of HPV-associated carcinomas will demonstrate block-type p16 expression by IHC. Of note, endometrial carcinomas (high grade endometrioid, serous and clear cell carcinomas) can also express p16; rarely p16 negative cases can occur from methylation-induced activation; and results of p16 were shown to be not as reproducible when performed on older or poorly preserved tissue blocks. When available, HR-HPV in situ hybridization (ISH) can be utilized, as it is as sensitive and more specific than p16 IHC. While PCR can confirm HPV infection, it has lower sensitivity and specificity, and does not provide ascertainment that HPV is present within the neoplastic cells. The IHC for p16 usually shows overexpression in both squamous and glandular components of ASC. Additional IHC stains such as CK7, carcinoembryonic antigen (CEA), and PAX8 may be utilized to highlight the glandular component, while p63 and p40 highlight the squamous component.

HPV-Independent Adenocarcinoma

HPV-independent endocervical adenocarcinomas include gastric, clear cell, mesonephric, and endometrioid types. Gastric type makes up approximately 10% to 15% of cervical adenocarcinomas (with up to 25% noted in Japan). It is found in association with Peutz-Jeghers syndrome (STK11 mutation), and while typically negative for p16 block expression, it may show mutated p53 expression in approximately 50% of cases. These tumors show a high prevalence of invasion, extrauterine spread and

present at an advanced stage. Mesonephric type demonstrates mesonephric (Wolffian) differentiation and is associated with mesonephric remnants. It typically is located deep in the lateral wall and histologically demonstrates architectural crowding, haphazard infiltration, atypia, mitotic activity, and necrosis. GATA-3 and CD10 IHC stains will be positive in the tumor and associated mesonephric remnants. Clear cell carcinomas make up 3% to 4% of endocervical adenocarcinomas, occurring sporadically or in association with in-utero diethylstilbestrol (DES) exposure. These tumors may demonstrate diffuse p16 expression despite the absence of HPV infection. In these instances, HR-HPV ISH can be utilized. Endometrioid carcinoma is quite uncommon, approximating 1% of primary endocervical adenocarcinomas, and may be present in the setting of endometriosis; however, a primary endometrial carcinoma must be ruled out. Utilizing a panel of immunohistochemical stains (vimentin, ER, p16, and monoclonal CEA) may be helpful in differentiating between endocervical and endometrial carcinoma. Typically, endometrioid adenocarcinoma will express vimentin and ER, while endocervical adenocarcinoma is positive for mCEA and p16 (when HPV-associated).

Primary Treatment

Note: Recommendations by stage are based on the revised 2018 FIGO staging by Bhatla et al.³⁸ However, trial data cited within this section primarily utilized the previous 2009 FIGO staging system.⁴⁰

The primary treatment of early-stage cervical cancer is either surgery or RT. Surgery is typically reserved for early-stage disease, fertility-preservation, and smaller lesions, such as stage IA, IB1, IB2, and selected IIA1.¹⁶³ The Panel agrees that concurrent chemoradiation is generally the primary treatment of choice for stages IB3 to IVA disease based on the results of five randomized clinical trials.^{164,165} Chemoradiation can also be used for patients who are not candidates for hysterectomy. Although few studies have assessed treatment specifically for

adenocarcinomas, they are typically treated in a similar manner to squamous cell carcinomas.¹⁶⁶⁻¹⁶⁸

Pelvic RT or chemoradiation will invariably lead to ovarian failure in patients undergoing premenopause.¹⁶⁹ To preserve intrinsic hormonal function, ovarian transposition may be considered before pelvic RT for select patients younger than 45 years of age with squamous cell cancers.^{170,171}

Important Phase III Clinical Trials Underpinning Treatment Recommendations

A randomized Italian study compared RT alone versus radical hysterectomy and lymphadenectomy in patients with clinical early-stage disease (stage IB–IIA).¹⁷² Adjuvant RT was given to those with parametrial extension, less than 3 cm of uninvolved cervical stroma, positive margins, or positive nodes. Identical outcomes were noted for patients treated with radiation versus surgery, with (or without) postoperative radiation, but higher complication rates were noted for the combined modality approach.

Concurrent chemoradiation, using platinum-containing chemotherapy (cisplatin alone [preferred] or cisplatin/fluorouracil), is the treatment of choice for stages IB3, II, III, and IVA disease based on the results of randomized clinical trials.¹⁷³⁻¹⁷⁸ These trials have shown that the use of concurrent chemoradiation results in a 30% to 50% decrease in the risk of death compared with RT alone. Although the optimal concurrent chemotherapy regimen to use with RT requires further investigation, these trials clearly established a role for concurrent cisplatin-containing chemoradiation. Based on these data, the NCI issued an alert stating that strong consideration should be given to using chemoradiation instead of RT alone for invasive cervical cancer.¹⁷⁸ Long-term follow-up of three of these trials has confirmed that concurrent cisplatin-containing chemoradiation improves PFS and OS when compared with RT with (or without) hydroxyurea.¹⁷⁹⁻¹⁸¹ A recent meta-analysis reported that

chemoradiotherapy leads to a 6% improvement in 5-year survival (HR, 0.81; $P < .001$).¹⁸² A large, population-based registry analysis in Canada ($n = 4069$) confirmed that chemoradiotherapy improved outcomes when compared with RT alone.¹⁸³

Although chemoradiation is tolerated, acute and long-term side effects have been reported.^{182,184,185} Concurrent single-agent cisplatin chemoradiation may be preferred over cisplatin/fluorouracil chemoradiation due to lesser toxicity.^{165,186} Concurrent carboplatin (preferred if cisplatin intolerant) or non-platinum chemoradiation regimens are options for patients who may not tolerate cisplatin-containing chemoradiation.^{182,187-192} Carboplatin has been added to the Guidelines as a preferred radiosensitizing agent for patients who are cisplatin intolerant.

Note that when concurrent chemoradiation is used, the chemotherapy is typically given when the external-beam pelvic radiation is administered.¹⁶⁵ The Panel believes that using “systemic consolidation” (ie, adding chemotherapy after chemoradiation) should only be used in clinical trials (eg, OUTBACK [ANZGOG-0902/GOG 274, NCT01414608] and RTOG 724 [NCT00980954]).¹⁹³

Early-Stage Disease

After careful clinical evaluation and staging, the primary treatment of early-stage cervical cancer is either surgery or RT. The treatment schema is stratified using the FIGO staging system. A fertility-sparing algorithm may be applied for select patients with stage IA, IB1, and certain cases of IB2 disease. Fertility-sparing surgery is generally not recommended for patients with small cell neuroendocrine tumors, gastric type adenocarcinoma, or adenoma malignum (minimal deviation adenocarcinoma) because of its high-risk nature and a paucity of data.

Stage IA1 Disease

Recommended options for stage IA1 disease depend on the results of cone biopsy and whether patients 1) want to preserve their fertility; 2) are medically operable; or 3) have LVSI. The extent of the lymphadenectomy depends on whether pelvic nodal disease and/or LVSI are present and the size of the tumors. SLN mapping can be considered.

Fertility-Sparing

For patients who desire fertility preservation, cone biopsy with or without pelvic lymphadenectomy is recommended.^{97,194,195}

The goal of cone biopsy is margins that are negative for invasive disease and high-grade squamous intraepithelial lesion (HSIL). For patients with negative margins after cone biopsy and no findings of LVSI, observation may be an option if fertility preservation is desired. For patients with positive margins after cone biopsy, options include repeat cone biopsy to better evaluate depth of invasion (to rule out stage IA2/IB disease) or a radical trachelectomy. In studies of patients who had positive margins after conization, predictors of residual disease included positive endocervical curettage, combined endocervical margin and endocervical curettage, and volume of disease.^{138,196,197} For patients with stage IA1 disease with LVSI, radical trachelectomy and SLN mapping/pelvic lymphadenectomy^{70,198-201} or conization (with negative margins) plus laparoscopic pelvic SLN mapping/lymphadenectomy is a reasonable strategy.

After childbearing is complete, hysterectomy can be considered for patients who have had either radical trachelectomy or a cone biopsy for early-stage disease if they have chronic, persistent HPV infection, they have persistent abnormal Pap tests, or they desire this surgery.

For young (<45 years) patients who are undergoing premenopausal with early-stage squamous cell carcinoma who opt for ovarian preservation (ie, hysterectomy only), the rate of ovarian metastases is low.^{202,203}

Non-Fertility-Sparing

For medically and technically operable patients with stage IA1 disease who do not desire fertility preservation, extrafascial (ie, simple) hysterectomy is commonly recommended for patients without LVSI and with either negative margins after cone biopsy or with positive margins for dysplasia. When medically operable, and if the margins are positive for carcinoma, modified radical hysterectomy is recommended with SLN mapping/pelvic lymphadenectomy (category 2B for node dissection). SLN mapping can be considered. If the margin is positive for dysplasia, extrafascial or modified radical hysterectomy is recommended. Physicians can also consider repeat cone biopsy to better evaluate depth of invasion to rule out stage 1A2/IB1 disease. For patients with positive margins for dysplasia or carcinoma and medically inoperable, Brachytherapy with or without pelvic external beam RT (EBRT) is recommended. If LVSI is present, then modified radical hysterectomy with SLN mapping/pelvic lymphadenectomy is recommended. For patients with negative margins after cone biopsy, observation is recommended for those who are medically inoperable or those who refuse surgery.

Stage IA2 Disease

Recommendations for stage IA2 depend upon whether a patient wishes to preserve their fertility and if the disease is medically operable.

Fertility-Sparing

For patients who wish to preserve their fertility, radical trachelectomy and pelvic lymphadenectomy are recommended. SLN mapping can also be considered. Cone biopsy followed by observation is another option if the margins are negative and pelvic lymphadenectomy is negative. For patients with stage IA2–IB1 with no evidence of LVSI and upon meeting all conservative surgery criteria, conization (with negative margin) and pelvic lymphadenectomy or SNL mapping can be done. The recommended surgical option for stage 1A1–IA2 with evidence of LVSI is radical

trachelectomy with pelvic lymphadenectomy. Cone biopsy can also be considered (with pelvic lymphadenectomy) and if positive margins, cone biopsy can be repeated or trachelectomy can be performed.

Non-Fertility-Sparing

For patients who are medically operable and who do not desire fertility preservation, recommended treatment includes either surgery or RT. The recommended surgical option for stage 1A2–IB1 with no evidence of LVSI and upon meeting conservative surgery criteria is extrafascial hysterectomy with pelvic lymphadenectomy. For patients in stage IA1–IA2 with LVSI, modified radical hysterectomy and bilateral pelvic lymphadenectomy SLN mapping can also be considered.^{197,204}

Pelvic EBRT with brachytherapy (traditionally 70–80 Gy to total point A dose) is a treatment option for patients who are medically inoperable or who refuse surgery.²⁰⁵ These doses are recommended for most patients based on summation of conventional external-beam fractionation and low dose-rate (40–70 cGy/h) brachytherapy equivalents. Treatment should be modified based on normal tissue tolerance, fractionation, and size of target volume or on biologic equivalence calculations when using high dose-rate brachytherapy.

Stage IB and IIA Disease

Depending on their stage and disease bulk, patients with stage IB or IIA tumors can be treated with surgery, RT, or concurrent chemoradiation. Fertility-sparing surgery is only recommended for patients with stage IB1 not meeting conservative surgery criteria or select cases of stage IB2 disease (see next section). A combined PET/CT scan can be performed to rule out extra pelvic disease before deciding how to treat these patients. Neck/chest/abdomen/pelvis/groin FDG-PET/CT is preferred to evaluate metastatic disease. A chest/abdomen/pelvis CT or FDG-PET/MRI can also be performed. Pelvic MRI with contrast is preferred to assess local disease extent. The GOG considers that surgical staging is an option for

patients with advanced cervical cancer. Radiologic imaging is recommended for assessing stage IB3 and IIA2 tumors (see *Principles of Imaging* in the NCCN Guidelines for Cervical Cancer).

Stage IB1: Fertility-Sparing

For patients who desire fertility preservation, radical trachelectomy and pelvic lymphadenectomy with (or without) para-aortic lymphadenectomy is an option for stage IB1 who do not meet the conservative surgery criteria, and select cases of IB2 disease, but typically only for tumors 2 cm or less in the NCCN Guidelines for Cervical Cancer.^{58,198-201,206} SLN mapping can also be considered. Tumors that are 2 to 4 cm must be carefully selected for a fertility-sparing approach as many of these patients may require postoperative adjuvant therapy due to pathologic risk factors (eg, Sedlis Criteria or positive nodes). However, some surgeons suggest that a 2 cm cutoff may be used for vaginal trachelectomy, whereas a 4 cm cutoff may be used for abdominal trachelectomy.²⁰⁷ In one study, oncologic outcomes were similar after 4 years when comparing radical trachelectomy with radical hysterectomy for patients with stage IB1 cervical carcinoma.⁵⁸

Stage IB1 or IB2 small cell neuroendocrine histology, gastric type adenocarcinoma, and adenoma malignum are not considered suitable for fertility-sparing surgery.

Stage IB and IIA: Non-Fertility-Sparing

The recommended surgical option for stage IB1 (low-risk) with no evidence of LVSI and upon meeting conservative surgery criteria is extrafascial hysterectomy with pelvic lymphadenectomy. For stage IB1 (not meeting conservative surgery criteria, IB2, and IIA1 disease, primary surgery consists of radical hysterectomy plus bilateral pelvic lymphadenectomy (category 1), with (or without) para-aortic lymphadenectomy (category 2B for para-aortic lymphadenectomy).^{172,208} SLN mapping can also be considered for stages IB1, IB2, and IIA1. Panel members feel that surgery is the most appropriate option for patients with

stage IB1, IB2, or IIA1 disease, whereas concurrent chemoradiation is the most appropriate option for those with stage IB3 or IIA2 disease based on randomized trials.^{172-174,176,177} Thus, the primary surgical option is a category 1 recommendation for patients with stage IB1, IB2, or IIA1 disease; however, primary chemoradiation is the category 1 recommendation for those with stage IB3 or IIA2 disease. Para-aortic lymphadenectomy may be performed for patients with larger tumors and suspected or known pelvic nodal disease. Some Panel members feel that a pelvic lymphadenectomy should be performed first and if negative, then a radical hysterectomy should be performed. If the lymph nodes are positive, then the hysterectomy should be abandoned; these patients should undergo chemoradiation. For patients with stage IB1 (who do not meet conservative surgery criteria), IB2, or IIA tumors (including those who are not candidates for hysterectomy), another option is combined pelvic EBRT and brachytherapy with (or without) concurrent platinum-containing chemotherapy. Preferred radiosensitizing regimens include cisplatin or carboplatin for patients who are cisplatin-intolerant. Other recommended regimens include capecitabine and mitomycin, gemcitabine and paclitaxel.^{190,209-211} Although concurrent chemoradiation has been proven effective in the definitive treatment of more advanced-stage disease, this approach has not been specifically studied in patients with stage IB1, IB2, or IIA1 disease. Careful consideration of the risk/benefit ratio should be undertaken in these patients with smaller tumors.

For patients with clinical stage IB3 or IIA2 tumors who are treated with definitive radiation, concurrent cisplatin-containing chemotherapy has been shown to significantly improve patient survival. The Panel recommends definitive EBRT with concurrent platinum-containing chemotherapy and brachytherapy (traditionally 75–80 Gy to total point A dose) (Category 1). Radical hysterectomy with pelvic lymphadenectomy with or without para-aortic lymphadenectomy is under category 2A. The addition of selective completion hysterectomy is a point of disagreement

among Panel members. This approach should only be considered in patients whose tumor shows a poor response with evidence of residual disease after chemoradiation + image-guided brachytherapy (IGBT) or in patients for whom IGBT is not feasible. Again, treatment should be modified based on normal tissue tolerance, fractionation, and size of target volume. Primary chemoradiation has a category 1 recommendation.^{173,174}

For stage IB3 or IIA2 tumors, the Panel had a major disagreement about recommending adjuvant hysterectomy (category 3) (also known as completion surgery) after primary chemoradiation.¹⁷³ Adjuvant hysterectomy after RT has been shown to improve pelvic control, but not overall survival, and is associated with increased morbidity.²¹² A Cochrane review examined whether the addition of hysterectomy to standard non-surgical treatments benefitted patients with locally advanced cervical cancer, finding insufficient data to demonstrate a survival benefit associated with surgery.²¹³ The morbidity is higher after completion surgery, but this may be reduced using a laparoscopic technique.²¹⁴⁻²¹⁷ Although routine completion hysterectomy is not typically performed, this approach may be considered in patients whose extent of disease or uterine anatomy precludes adequate coverage by brachytherapy.

Advanced Disease

This category has traditionally included patients with stage IIB to IVA disease (ie, locally advanced disease). However, many oncologists now include patients with IB3 and IIA2 disease in the advanced disease category. For patients with more advanced tumors who are undergoing primary chemoradiation, the volume of RT is critical and guided by assessment of nodal involvement in the pelvic and para-aortic nodes. Radiologic imaging studies (neck/chest/abdomen/pelvis/groin FDG-PET/CT (preferred) or chest/abdomen/pelvis CT to evaluate for metastatic disease^{218, 219} are recommended for stage IB2 or greater disease, especially for evaluation of nodal or extra pelvic tumor (see

Principles of Imaging in the NCCN Guidelines for Cervical Cancer). Pelvic MRI with contrast is preferred to describe local disease extent and assist in radiation treatment planning. However, needle biopsy of extrauterine abnormality can be considered for questionable imaging findings. Surgical staging (ie, extraperitoneal or laparoscopic lymphadenectomy) is also an option (category 2B) for these patients.²²⁰ Surgical staging may also detect microscopic nodal disease that is not discernable with radiologic imaging.²²¹

For patients without nodal disease or with disease limited to the pelvis only through surgical staging, treatment consists of pelvic EBRT with concurrent platinum-containing chemotherapy and brachytherapy (category 1).^{164,165,174,176-178,222} Currently, acceptable concurrent platinum-containing regimens include either weekly cisplatin (preferred), carboplatin (preferred if cisplatin intolerant), or cisplatin/fluorouracil, given every 3 to 4 weeks during RT. Pembrolizumab may be added with chemoradiotherapy (CRT) for patients with FIGO 2014 stage III–IVA cervical cancer based on KeyNote A18 trial (See *Systemic therapy* section). An international phase III randomized trial reported that concurrent cisplatin/gemcitabine and EBRT followed by 2 additional cycles of cisplatin/gemcitabine after RT improved PFS and OS when compared with a standard regimen of concurrent cisplatin with pelvic EBRT.²²³ However, this trial is controversial because of changes in its statistical design and because the reported superior regimen of concurrent cisplatin/gemcitabine and EBRT has unresolved toxicity issues.²²³⁻²²⁶

For patients with para-aortic lymph node positive by surgical staging (FIGO 2018 IIIC2p), further radiologic workup for metastatic disease is recommended. With no distant metastasis, extended-field EBRT with concurrent platinum-based chemotherapy and brachytherapy is recommended. Concurrent platinum-containing chemotherapy with EBRT utilizes cisplatin as a single agent (or carboplatin if cisplatin intolerant).

Pembrolizumab may be added with chemoradiation for patients with FIGO 2014 stage III–IVA cervical cancer.

Patients with positive adenopathy by CT, MRI and/or FDG-PET/CT with pelvic node positive and para-aortic lymph node negative (by imaging or surgical staging), pelvic EBRT with concurrent chemotherapy and brachytherapy is recommended as category 1. Para-aortic lymph node EBRT can be added to the regimen.

However, for patients with positive para-aortic and pelvic lymph nodes by imaging, imaging workup for metastatic disease is recommended. Extended-field EBRT, concurrent platinum-containing chemotherapy, and brachytherapy are recommended. Patients with positive para-aortic lymph nodes who are positive for distant metastases are treated with systemic chemotherapy with (or without) individualized EBRT.²²⁷

Metastatic Disease

For patients who present with distant metastatic disease (ie, stage IVB), primary treatment is often platinum-containing chemotherapy (see *Therapy for Metastatic Disease* in this Discussion). In these situations, individualized EBRT may be considered for control of pelvic disease and other symptoms.²²⁷

Adjuvant Treatment

Adjuvant treatment is indicated after radical hysterectomy depending on surgical findings and disease stage. Observation is appropriate for patients with stage IA2, IB, or IIA1 disease who have negative nodes, negative margins, negative parametria, and no cervical risk factors after radical hysterectomy (Sedlis Criteria). However, adjuvant treatment is indicated after radical hysterectomy if pathologic risk factors are discovered.

Pelvic EBRT is recommended (category 1) with (or without) concurrent platinum-containing chemotherapy (category 2B for chemotherapy) for patients with stage IA2, IB, or IIA1 disease who have negative lymph nodes after surgery but have large primary tumors, deep stromal invasion, and/or LVSI.^{135,228-231} Recommended radiosensitizing regimens include cisplatin (preferred), carboplatin (preferred if cisplatin intolerant), or capecitabine/mitomycin, gemcitabine or paclitaxel.

Adjuvant pelvic RT alone versus no further therapy was tested in a randomized trial (GOG 92) of selected patients with node-negative stage IB carcinoma of the cervix after hysterectomy and pelvic lymphadenectomy.¹³⁵ Patients were considered to have “intermediate-risk” disease and were eligible for this trial if they had at least two of the following risk factors (commonly referred to as Sedlis Criteria): 1) greater than one-third stromal invasion; 2) capillary lymphatic space involvement; or 3) cervical tumor diameters more than 4 cm. Patients with positive lymph nodes or involved surgical margins were excluded. At 2 years, the recurrence-free rates were 88% for adjuvant RT versus 79% for the no-adjuvant-treatment group. After long-term follow-up (12 years), an updated analysis confirmed that adjuvant pelvic RT increased PFS; a clear trend towards improved overall survival was noted ($P = .07$).²²⁸ The role of concurrent cisplatin/RT in patients with intermediate-risk disease is currently being evaluated in an international phase III randomized trial (GOG 263, NCT01101451).

Potentially important risk factors for recurrence may not be limited to the Sedlis Criteria” (ie, stromal invasion, LVSI, primary tumor size). Additional risk factors for consideration include tumor histology (eg, adenocarcinoma component)^{136,137} and close or positive surgical margins.^{138,139}

Postoperative pelvic EBRT with concurrent platinum-containing chemotherapy (category 1)¹⁷⁵ with (or without) vaginal brachytherapy is recommended for patients with positive pelvic nodes, positive surgical

margin, and/or positive parametrium; these patients are considered to have “high-risk” disease. Vaginal brachytherapy may be a useful boost for those with positive vaginal mucosal margins. Adjuvant concurrent chemoradiation significantly improves overall survival for patients with high-risk, early-stage disease (those with positive pelvic nodes, parametrial extension, and/or positive margins) who undergo radical hysterectomy and pelvic lymphadenectomy.¹⁷⁵ The Intergroup trial 0107/GOG 109 showed a statistically significant benefit of adjuvant pelvic radiation with concurrent cisplatin and fluorouracil in the treatment of patients with stage IA2, IB, or IIA disease who had positive lymph nodes, positive margins, and/or microscopic parametrial involvement found at surgery.¹⁷⁵ A study re-evaluated these findings from GOG 109 in a population-based cohort (n = 3053) in the National Cancer Database, confirming the survival benefit of adjuvant chemoradiation but suggesting that this benefit may be best realized in patients with lymph node involvement.²³²

Depending on the results of primary surgery, imaging may be recommended to determine whether distant metastases are present. In patients who are positive for distant metastases, perform biopsy of suspicious areas as indicated. For patients without distant metastases, recommended treatment is extended-field EBRT (including pelvic and para-aortic lymph nodes) with concurrent platinum-containing chemotherapy and with (or without) brachytherapy. Recommended radiosensitizing regimens include cisplatin (preferred), carboplatin (preferred if cisplatin intolerant), or capecitabine/mitomycin, gemcitabine or paclitaxel. For patients with distant metastases, recommended treatment is systemic chemotherapy with (or without) individualized EBRT.²²⁷

Although neoadjuvant chemotherapy followed by surgery has been used in areas where RT is not available, data suggest no improvement in survival when compared with surgery alone for early-stage cervical

cancer²³³⁻²³⁵ or locally advanced cervical cancer.^{236,237} A meta-analysis of data on patients with stage IB1 to IIA cervical cancer found that neoadjuvant chemotherapy may reduce the need for adjuvant RT by decreasing tumor size and metastases, but indicated no overall survival benefit.²³⁷ However, data from a second meta-analysis suggested that response to neoadjuvant chemotherapy was a strong prognostic factor for PFS and OS.^{238,239} Outside of the clinical trial, the Panel does not recommend the use of neoadjuvant chemotherapy.

Surveillance

The Panel agrees with the new Society of Gynecologic Oncology’s (SGOs) recommendations for post-treatment surveillance.²⁴⁰ The recommended surveillance is based on the patient’s risk for recurrence and personal preferences. History and physical examinations are recommended every 3 to 6 months for 2 years, every 6 to 12 months for another 3 to 5 years, and then annually. Patients with high-risk disease can be assessed more frequently (eg, every 3 months for the first 2 years) than patients with low-risk disease (eg, every 6 months).

Annual cervical/vaginal cytology tests can be considered as indicated for detection of lower genital tract dysplasia (eg, for those who have had fertility-sparing surgery). Some clinicians have suggested that rigorous cytology follow-up is not warranted because of studies stating that Pap smears did not detect recurrences in patients with stage I or II cervical cancer who were asymptomatic after treatment.²⁴⁰⁻²⁴² Noting the inherent differences between these patients and the general screening population, the Panel does not recommend workup of low-grade squamous dysplasia detected during surveillance, but suggests that patients should follow up with a provider with specific expertise in this area. It is important to emphasize good clinical evaluation and a high index of suspicion, because the detection rate of recurrent cervical cancer is low using cervical and vaginal cytology alone.²⁴³

NCCN Guidelines Version 3.2024

Cervical Cancer

For patients with stage I disease, follow-up imaging should be based on symptomatology and clinical concern for recurrent/metastatic disease, such as abnormal physical exam finding or new pelvic, abdominal, or pulmonary symptoms. If fertility-sparing treatment was provided, pelvic MRI should be considered 6 months after surgery and yearly for 2 to 3 years. Neck/chest/abdomen/pelvis/groin FDG-PET/CT can be considered if metastasis is suspected.^{244,245} For patients with stage II disease or greater, neck/chest/abdomen/pelvis/groin FDG-PET/CT (preferred) or chest/abdomen/pelvis CT with contrast should be performed within 3 to 6 months of completing therapy; pelvic MRI is optional. Additional imaging should be guided by symptomatology and clinical concern for recurrent/metastatic disease. Specific indications and recommendations for surveillance imaging are detailed in *Principles of Imaging* in the NCCN Guidelines for Cervical Cancer.^{219,240,244,246-252}

Many other tests remain optional based on clinical indications, such as semiannual CBCs, blood urea nitrogen (BUN), and serum creatinine determinations. Patients with persistent or recurrent disease need to be evaluated using additional imaging studies as clinically indicated, biopsy with or without examination under anesthesia (EUA) and surgical exploration in selected cases followed by therapy for relapse (see *Therapy for Relapse* section).²⁵³ Comprehensive molecular profiling as determined by FDA-approved assay or a validated test performed in CLIA certified laboratory can be considered for better selection of systemic therapy. If tissue biopsy of metastatic site is not feasible or tissue is not available, comprehensive genomic profiling via a validated plasma circulating tumor DNA (ctDNA) assay can be considered.

Education of patients regarding symptoms suggestive of recurrence is recommended (eg, vaginal discharge; weight loss; anorexia; pain in the pelvis, hips, back, or legs; persistent coughing). Patients should also be counseled on healthy lifestyle, obesity, nutrition, exercise, sexual health,

hormone replacement therapy, and potential long-term and late effects of treatment. Smoking cessation and abstinence should be encouraged.²⁴⁰ See the [NCCN Guidelines for Survivorship](#), the [NCCN Guidelines for Smoking Cessation](#), and <https://www.cancer.org/cancer/survivorship>.

Patients who have received RT for cervical cancer may experience vaginal stenosis and dryness and should receive education on important issues regarding sexual health and vaginal health. Providers should inform patients about regular vaginal intercourse and/or vaginal dilator use and on the use of vaginal moisturizers/lubricants (eg, estrogen creams). Anecdotal evidence suggests that vaginal dilators may be used to prevent or treat vaginal stenosis.²⁵⁴ Dilator use can start 2 to 4 weeks after RT is completed and can be performed indefinitely.

Cervical cancer survivors are at risk for second cancers.²⁵⁵ Data suggest that patients who undergo RT for pelvic cancers are at risk for radiation-induced second cancers, especially at radiated sites near the cervix (eg, colon, rectum/anus, urinary bladder); therefore, careful surveillance is appropriate for these patients.^{256,257}

Therapy for Relapse

Recurrences should be proven by biopsy before proceeding to treatment planning for recurrent disease.

Locoregional Recurrence

Patients with a localized recurrence of cervical cancer after initial treatment may be candidates for radical retreatment; options include: 1) RT and/or chemotherapy; or 2) surgery.^{164,258} After treatment for relapse, long-term, disease-free survival rates of approximately 40% have been reported in some situations.²⁵⁹

For patients who experience locoregional recurrences who have not undergone previous RT or who experience recurrences outside of the

previously treated RT field, therapy for relapse includes tumor-directed EBRT and concurrent platinum containing chemotherapy and/or brachytherapy; surgical resection can be considered if feasible. Typically, the chemoradiation for recurrence uses cisplatin as a single agent or carboplatin (if cisplatin intolerant).^{260,261} However, in those patients who have relapsed soon after completing initial chemoradiation with these regimens, other systemic therapy options might be considered or best supportive care could be offered (see [NCCN Guidelines for Palliative Care](#)).

Patients with central pelvic recurrent disease after RT should be evaluated for pelvic exenteration, with (or without) intraoperative RT (IORT), although IORT is category 3.²⁶²⁻²⁶⁹ Surgical mortality is generally 5% or less, with survival rates approaching 50% in carefully selected patients.²⁶⁵ Concomitant measures with these radical procedures include adequate rehabilitation programs dealing with the psychosocial and psychosexual consequences of the surgery as well as reconstructive procedures.^{264,270-272} Although exenteration is the common surgical approach in patients who have previously received radiation with isolated central pelvic relapse, radical hysterectomy or brachytherapy or individualized EBRT with or without concurrent platinum containing chemotherapy with cisplatin or carboplatin if cisplatin intolerant may be an option in carefully selected patients with small central lesions (<2 cm).

For patients with noncentral recurrent disease, options include EBRT with (or without) concurrent platinum containing chemotherapy, resection with (or without) IORT (category 3 for IORT), or systemic therapy or best supportive care (see the [NCCN Guidelines for Palliative Care](#)), or participation in a clinical trial.

Patients who experience recurrence after second-line definitive therapy, either surgery or RT, have a poor prognosis. They can be treated with

systemic therapy or best supportive care or can be enrolled in a clinical trial.

Therapy for Metastatic Disease

Patients who develop distant metastases, either at initial presentation or at relapse, are rarely curable. Comprehensive molecular profiling as determined by FDA-approved assay, or a validated test performed in CLIA certified laboratory can be considered for better selection of systemic therapy. If tissue biopsy of metastatic site is not feasible or tissue is not available, comprehensive genomic profiling via a validated plasma ctDNA assay can be considered to guide appropriate biomarker directed second line therapy. For highly selected patients with isolated distant metastases amendable to local treatment,²⁷³ occasional long-term survival has been reported with: 1) surgical resection with (or without) EBRT; 2) local ablative therapies with (or without) EBRT; or 3) EBRT with (or without) chemotherapy. Systemic adjuvant chemotherapy can be considered. For example, patients who may benefit from aggressive local therapy for oligometastatic disease include those with nodal, lung, liver, or bone metastases.^{274,275} Following local therapy, additional adjuvant chemotherapy can be considered. For most other patients with distant metastases, an appropriate approach is a clinical trial, chemotherapy, or best supportive care (see [NCCN Guidelines for Palliative Care](#)).

The palliation of pelvic recurrences in heavily irradiated sites that are not amenable to local pain control techniques or to surgical resection is difficult.²⁷⁶ These sites are generally not responsive to chemotherapy. Adequately palliating the complications of pain and fistulae from these recurrences is clinically challenging (<http://emedicine.medscape.com/article/270646-overview>). However, short courses of RT may provide symptomatic relief to patients with bone metastases, painful para-aortic nodes, or supraclavicular adenopathy.^{227,277,278}

Chemotherapy is often recommended for patients with extra pelvic metastases or recurrent disease who are not candidates for RT or exenterative surgery. Patients whose disease responds to chemotherapy may have relief from pain and other symptoms. If cisplatin was previously used as a radiosensitizer, combination platinum-based regimens are preferred over single agents in the metastatic disease setting based on several randomized phase III trials (see next paragraph).^{279,280} However, responses to chemotherapy are often of short duration and survival is rarely increased.

Systemic Therapy Recommendations

Chemoradiation for Locally Advanced Cervical Cancer

Concurrent chemoradiation, using platinum containing chemotherapy (cisplatin alone [preferred]), is the treatment of choice for stages IB3, II, III, and IVA disease based on the results of randomized clinical trials. These trials have shown that the use of concurrent chemoradiation results in a 30% to 50% decrease in the risk of death compared with RT alone. Long-term follow-up of three trials have confirmed that concurrent cisplatin containing chemoradiation improves PFS and OS when compared with RT with (or without) hydroxyurea.¹⁷⁹⁻¹⁸¹ Cisplatin remains as the preferred radiosensitizing agent in the primary treatment for patients with locally advanced cervical cancer when used concomitantly with EBRT and carboplatin as a preferred radiosensitizing agent for patients who are cisplatin intolerant.²⁸¹ When cisplatin and carboplatin are unavailable. The other recommended options are capecitabine/mitomycin IV, gemcitabine, and paclitaxel as radiosensitizers based on a few early-phase studies that have shown their efficacy and tolerability when administered concomitantly with radiation.^{190,209,210} A phase 3, randomized trial, enrolling 926 patients with locally advanced cervical cancer of stage IIB–IVA, evaluated the efficacy of RT plus concurrent chemotherapy consisting of oral 5-fluorouracil/mitomycin as compared to RT only, RT plus adjuvant chemotherapy (5-fluorouracil) or RT plus concurrent chemoradiotherapy

plus adjuvant chemotherapy.¹⁹⁰ Although acute side effects were more prevalent in the concurrent arms and the OS was not significant between the arms, the RT plus concurrent chemotherapy arm showed the least locoregional recurrence and the highest 5-year DFS when compared with the other arms. In particular, the difference in DFS and OS rate was highly significant when comparing the concurrent chemoradiation arm with the RT only arm ($P = .0001$). Several studies have shown that although 5-fluorouracil/mitomycin combined with RT was effective, the combination is also associated with relatively higher toxicity rates and should be used with caution.^{282,283} The efficacy and safety of gemcitabine combined with pelvic radiation was tested in 19 patients with chemo-naïve, advanced stage IIIB cervical cancer and showed a CR of 89.5% and PR of 5.3% for an ORR of 94.7%. The OS at median follow-up time of 19.9 months was 100% with DFS of 84.2%. Due to gemcitabine's high potency as a radiosensitizer, it requires reduced dosing when used concurrently with radiation to avoid radiation toxicity.²⁰⁹ In a comparative study, the disease control and toxicity profile were found to be similar between cisplatin and gemcitabine.²⁸⁴ The benefit of paclitaxel alone as a radiosensitizer has not been extensively studied in the literature and there are only a few known preclinical or early-phase studies of its efficacy. In a pilot study to evaluate paclitaxel with RT, CR was achieved by 8 out of 13 patients with locally advanced cervical cancer and by 4 out of 6 patients treated with a recurrent disease.²¹¹ Although chemoradiation is tolerated, acute and long-term side effects have been reported.^{182,184,185} Due to significant toxicity concerns associated with these agents, cisplatin or carboplatin is a preferred agent over other non-platinum chemoradiation regimens.

A multicenter, randomized, double-blind, placebo-controlled trial KEYNOTE-A18 (NCT04221945) evaluated the efficacy of concurrent platinum-containing chemotherapy (CCRT) with EBRT utilizing cisplatin as a single agent with pembrolizumab in 1060 eligible patients with newly diagnosed, previously untreated, high-risk locally advanced cervical

cancer (FIGO 2014 stage IB2–IIB with node-positive disease or stage III–IVA). **Pembrolizumab + CCRT** showed **a statistically significant and clinically meaningful improvement in PFS and a favorable trend in OS** compared with placebo + CCRT in patients with high-risk locally advanced cervical cancer.²⁸⁵ In an exploratory subgroup analysis in the 596 patients with FIGO 2014 stage III–IVA disease, the PFS HR estimate was 0.59 (95% CI: 0.43, 0.82), and 21% of patients in the pembrolizumab arm experienced a PFS event compared to 31% of patients in the placebo arm. In contrast, in an exploratory subgroup analysis in the 462 patients with FIGO 2014 stage IB2–IIB disease, the PFS HR estimate was 0.91 (95% CI: 0.63, 1.31), indicating that the PFS improvement in the overall population was primarily attributed to patients with FIGO 2014 stage III–IVA disease. **Based on FDA approval in 2024, a footnote was added in the preferred regimen for chemoradiation in the version 2.2024 that in the concurrent platinum-containing chemotherapy with EBRT setting, pembrolizumab may be added ONLY for patients with FIGO 2014 stage III–IVA cervical cancer.**

The NCCN Panel has noted for all chemoradiation agents that the cost and toxicity profiles of these radiosensitizing agents should be considered when selecting an appropriate regimen for treatment and have strongly expressed that this is especially critical when these regimens are being used for extended field radiation therapy where toxicities may be more severe.

Systemic Therapy for Recurrent or Metastatic Cervical Cancer

The estimated 5-year survival rate for patients with early-stage cervical cancer is more than 90% whereas the curative options for advanced stage disease are limited.²⁸⁶ Systemic therapy with or without radiation forms the basis of treatment of patients with recurrent or metastatic disease.

First-Line Systemic Therapy Options for Recurrent or Metastatic Disease

Preferred Regimens

Pembrolizumab Plus Chemotherapy with or without Bevacizumab as First-line Therapy

Presently, the Guidelines include two immunotherapy-based regimens as preferred, first-line therapy options for the treatment of PD-L1–positive recurrent or metastatic cervical cancer. Pembrolizumab combined with chemotherapy with or without bevacizumab regimens is the preferred, category 1 treatment option based on the results of the Keynote-826 study.¹⁴³ In the primary analysis of the phase 3, Keynote-826 trial, which enrolled 617 patients (548 with PD-L1–positive CPS ≥ 1 tumors; 317 patients with CPS ≥ 10) with previously untreated persistent, recurrent, or metastatic cervical cancer, the addition of pembrolizumab to chemotherapy with or without bevacizumab improved PFS and overall survival versus the placebo group (PFS, 10.4 vs. 8.2 months, respectively; HR, 0.65; 95% CI, 0.53–0.79; $P < .001$, and OS at 24 months: 50.4% vs. 40.4%, respectively; HR, 0.67; 95% CI, 0.54–0.84; $P < .001$). The ORR was significantly higher in the pembrolizumab arm as compared to the placebo group in the patients with PD-L1–positive (CPS ≥ 1) tumors (68.1% vs. 50.2%). The FDA approved pembrolizumab plus chemotherapy, with or without bevacizumab for patients with persistent, recurrent, or metastatic cervical cancer whose tumors express PD-L1 (CPS ≥ 1). In the final, updated analysis of the trial results, the addition of pembrolizumab to chemotherapy with or without bevacizumab continued to show significant survival benefits in the PD-L1–positive (CPS ≥ 1) tumors at a median follow-up of 39.1 months with median OS and PFS of 28.6 and 10.5 months versus 16.5 and 8.2 months in the pembrolizumab plus chemotherapy arm versus the placebo plus chemotherapy arm, respectively (HR, 0.60; 95% CI, 0.49–0.74; $P < .0001$).²⁸⁷ The NCCN Panel continues to recommend pembrolizumab in patients whose tumors

express PD-L1 (CPS ≥ 1) as determined by an FDA-approved assay, or a validated test performed in a CLIA-certified laboratory.

The recently published patient-reported outcomes (PROs) from KEYNOTE-826 also shows that the addition of pembrolizumab to chemotherapy with or without bevacizumab did not negatively affect health-related quality of life. The exploratory subgroup analyses of patients with persistent, recurrent, or metastatic adenocarcinoma, adenosquamous carcinoma, or squamous cell carcinoma of the cervix that had not been treated with systemic chemotherapy and was not amenable to curative treatment suggest that adding pembrolizumab to chemotherapy with or without bevacizumab improved OS across all subgroups defined by use of bevacizumab (yes or no), choice of platinum (carboplatin or cisplatin), prior CRT exposure only (yes or no), and histologic type (squamous or non-squamous) in patients with PD-1–positive tumors (defined as a CPS ≥ 1).²⁸⁸

The platinum-based chemotherapy (cisplatin or carboplatin)/paclitaxel with bevacizumab have been extensively investigated in clinical studies and is among the preferred, first-line treatment option for patients with recurrent/metastatic cervical cancer in the NCCN Guidelines (based on GOG 240 trial). The cisplatin/paclitaxel/bevacizumab regimen is category 1 in this disease setting.²⁸⁹

A randomized phase III trial (GOG 240) studied the addition of bevacizumab to combination chemotherapy regimens (cisplatin/paclitaxel/bevacizumab or topotecan/paclitaxel/bevacizumab) in 452 patients in the first-line setting of metastatic, persistent, or recurrent cervical cancer. Analysis of pooled data from the two chemotherapy regimens revealed significant improvements in overall survival among patients receiving bevacizumab (16.8 vs. 13.3 months; $P = .007$).²⁹⁰ While bevacizumab led to higher toxicity (eg, hypertension, thromboembolic events, gastrointestinal fistula), it was not associated with a statistically significant decrease in patient-reported quality of life ($P = .27$).²⁹¹ A 2017

systemic review and meta-analysis of data from 19 trials of systemic therapy for patients with recurrent, persistent, or metastatic cervical cancer found a trend towards improved OS for the addition of bevacizumab to cisplatin/paclitaxel or topotecan/paclitaxel when compared with all other non-bevacizumab–containing chemotherapy regimens.²⁹²

The published data from a phase III randomized trial (JCOG0505) suggested that carboplatin/paclitaxel was non-inferior to cisplatin/paclitaxel in 253 patients with metastatic or recurrent cervical cancer.²⁹³ Many physicians use carboplatin/paclitaxel because of ease of administration and tolerability.²⁹⁴ Results from JCOG0505 showed that the carboplatin/paclitaxel (TC) regimen was non-inferior to cisplatin/paclitaxel (TP) in terms of median overall survival (18.3 months for TP vs. 17.5 months for TC; HR = 0.994 [90% CI, 0.79–1.25]; $P = .032$) and non-hospitalization periods were significantly longer for patients receiving TC.²⁹³ However, among patients who had not received prior cisplatin, OS for TC and TP was 13.0 and 23.2 months, respectively (HR = 1.571; 95% CI, 1.06–2.32).²⁹³ Based on these data, the Panel recommends carboplatin/paclitaxel as a preferred category 1 option for patients who have received prior cisplatin therapy (category 2A for other indications).

A systematic review of the data on cisplatin/paclitaxel and carboplatin/paclitaxel regimens also suggested that lower toxicity carboplatin-based regimens appear to be an equally effective alternative to cisplatin-containing regimens for treating recurrent or metastatic cervical cancer.²⁹⁵ Based on the collective findings from GOG 240 and JGOG0505, the Panel has opted to include carboplatin/paclitaxel/bevacizumab as an additional preferred regimen for recurrent or metastatic cervical cancer (category 2A).

Other Recommended Regimens

Cisplatin is generally regarded as the most active agent and is recommended as the preferred first-line single-agent chemotherapy option

for recurrent or metastatic cervical cancer; reported response rates are approximately 20% to 30%, with an occasional complete response.^{279,296-298} Overall survival with cisplatin is approximately 6 to 9 months. Both carboplatin and paclitaxel have each been reported to be tolerable and efficacious and are also possible first-line single-agent chemotherapy options.²⁹⁹⁻³⁰³ Therefore, palliation with single agents—cisplatin, carboplatin, or paclitaxel—is a reasonable approach in patients with recurrent disease not amenable to surgical or radiotherapeutic approaches. However, most patients who develop metastatic disease have received concurrent cisplatin/RT as primary treatment and may no longer be sensitive to single-agent platinum therapy.^{279,280}

The Panel recommends single agent cisplatin and carboplatin as other recommended regimens. In previous versions of the Guidelines, cisplatin was placed under “preferred, first-line single-agent” category. However, based on the Panel’s clinical judgement, as more effective treatment options are increasingly being available in the first-line setting, platinum-based single-agent chemotherapy has been reserved as alternate options under other recommended regimens in the Guidelines.

The Panel has continued to recommend other platinum-containing combination regimens, such as cisplatin/paclitaxel (category 1), carboplatin/paclitaxel (category 1), topotecan/paclitaxel/bevacizumab (category 1), topotecan/paclitaxel, and cisplatin/topotecan as appropriate alternate options under the other recommended regimens category.^{279,280,290,304-306} A randomized phase III study (GOG 169) in 264 patients compared cisplatin/paclitaxel versus cisplatin alone for metastatic, recurrent, or persistent cervical cancer. Patients receiving the 2-drug combination had a higher response rate (36% vs. 19%) and improved PFS (4.8 vs. 2.8 months; $P > .001$) compared to single-agent cisplatin, although no improvement was seen in median survival.²⁷⁹ Patients who responded to cisplatin/paclitaxel had a significant improvement in quality of life.

Another randomized phase III study (GOG 179) in 294 patients investigated cisplatin/topotecan versus cisplatin alone for recurrent or persistent cervical cancer. The topotecan combination regimen was shown to be superior to single-agent cisplatin with respect to overall response rate (27% vs. 13%, $P = .004$), PFS (4.6 vs. 2.9 months; $P = .014$), and median survival (9.4 vs. 6.5 months; $P = .017$).²⁸⁰ The FDA has approved cisplatin/topotecan for advanced cervical cancer. However, the cisplatin/paclitaxel or carboplatin/paclitaxel regimens are less toxic and easier to administer than cisplatin/topotecan.³⁰⁷

A phase III trial (GOG 204) compared 4 cisplatin-doublet regimens (cisplatin/paclitaxel, cisplatin/topotecan, cisplatin/gemcitabine, and cisplatin/vinorelbine) in 513 patients with advanced metastatic or recurrent cancer.³⁰⁶ The trial was closed early based on futility analysis, because it was apparent that the cisplatin/topotecan, cisplatin/gemcitabine, and cisplatin/vinorelbine regimens were not superior to the control arm of cisplatin/paclitaxel. No significant differences in overall survival were seen; however, the trends for response rate, PFS, and overall survival (12.9 vs. 10 months) suggest that cisplatin/paclitaxel is superior to the other regimens. Cisplatin/paclitaxel was associated with less thrombocytopenia and anemia (but with more nausea, vomiting, infection, and alopecia) than the other regimens. While topotecan/paclitaxel was not shown to be superior to cisplatin/paclitaxel, it may be considered as an alternative in patients who are not candidates for cisplatin.²⁹⁰

Based on previous studies, cisplatin/paclitaxel (category 1) and carboplatin/paclitaxel have become the most widely used systemic regimens for metastatic or recurrent cervical cancer. However, for patients who may not be candidates for taxanes, cisplatin/topotecan remains a reasonable alternative regimen.²⁸⁰ In 2019, the Panel voted to remove cisplatin/gemcitabine as a first-line combination therapy option.

Non-platinum regimens are also being studied and may be considered in patients who cannot tolerate platinum-based chemotherapy.³⁰⁸

Second-line/Subsequent Systemic Therapy Options for Recurrent or Metastatic Cervical Cancer

The treatment options for patients with disease progression after first-line therapies have mostly been of limited effect with low response rates to second-line and beyond chemotherapies and median PFS of around 3 to 6 months.^{309,310}

Immunotherapy as Preferred, Second-line/Subsequent Therapy

Increasingly available data from several prospective studies have demonstrated the effectiveness of immunotherapies or specific biomarker-based therapies in the setting of disease progression and has significantly transformed the management of cervical cancer. In addition, many biomarker-specific therapies have demonstrated meaningful clinical efficacy and durability regardless of the underlying tumor type leading to an increase in tumor-agnostic regulatory approvals.

Pembrolizumab as a Preferred, Second-line/Subsequent Therapy

Pembrolizumab is an FDA-approved therapy for patients with recurrent or metastatic cervical cancer with disease progression on or after chemotherapy for PD-L1–positive tumors (CPS ≥ 1). It is also approved for unresectable or metastatic MSI-H/dMMR or TMB-H solid tumors that have progressed following prior treatment and who have no satisfactory alternative treatment options. In the NCCN Guidelines, pembrolizumab monotherapy is the preferred, second-line therapy option for recurrent/metastatic MSI-H/dMMR or TMB-H or PD-L1–positive tumors based on the results from Keynote-028 (phase 1b) and Keynote-158 (phase 2) trials.^{149,311,312}

Tisotumab vedotin-tftv as a Preferred, Second-line/Subsequent Therapy

Tisotumab vedotin-tftv is an antibody-drug conjugate directed against tissue factor and monomethyl auristatin E, a potent inhibitor of cell division. The tissue factor is aberrantly expressed across multiple solid tumors and is associated with poor clinical outcomes and an increase in metastatic potential. Studies have indicated that tissue factor is highly prevalent in cervical cancer and might have a role in disease progression and poor patient outcome in the clinic.³¹³ The phase 1/2, InnovaTV-201 trial enrolled 147 patients with pretreated advanced or metastatic solid tumors, including 34 patients with advanced cervical cancer, in the dose expansion phase of the study to evaluate the safety and durability of tisotumab vedotin-tftv.³¹⁴ The ORR was 15.6% (95% CI, 10.2–22.5) with median DOR 5.7 months (95% CI, 3.0–9.5) and the median PFS was 3 months (95% CI, 2.8–4.1). Among the patients with cervical cancer, the ORR was achieved by 9 out of 34 patients (26.5%, 95% CI, 12.9–44.4). The study protocol was further amended to include additional patients in the cervical cancer expansion cohort. Among a total of 55 patients enrolled in the cervical cancer cohort, confirmed ORR was achieved in 22% (95% CI, 12–35) with median DOR 6.0 months (95% CI, 1–9.7) and median PFS of 4.1 months (1.7–6.7).³¹⁵ This study was followed by the InnovaTV-204 trial, a phase 2 single-arm study that evaluated the efficacy of tisotumab vedotin-tftv in 102 patients with recurrent or metastatic cervical cancer who had progressed on previous systemic therapy.³¹⁶ At the median follow-up of 10 months, the confirmed ORR was 24% (95% CI, 16–33) which included 7% CR and 17% PR, and the median DOR was 8.3 months (95% CI, 4.2 – NR). Following the results from InnovaTV-201 and InnovaTV-204 trials that showed clinically meaningful and durable activity of tisotumab vedotin-tftv against pretreated recurrent/metastatic cervical cancer, the FDA granted accelerated approval for or adult patients with recurrent or metastatic cervical cancer with disease progression on or after chemotherapy.³¹⁷ The results from the phase 3, randomized, InnovaTV-301 /ENGOT-cx12/GOG-3057 trial were recently published at

NCCN Guidelines Version 3.2024

Cervical Cancer

ESMO 2023.³¹⁸ Among the 502 patients that were randomized (TV: 253; chemotherapy: 249); The TV arm had a 30% reduction in risk of death vs chemotherapy (HR, 0.70; 95% CI, 0.54–0.89; $P = .0038$), The results showed that at a median follow-up of 10.8 months (95% CI, 10.3–11.6), with significantly longer median OS (11.5 months [95% CI, 9.8–14.9] vs. 9.5 months [95% CI, 7.9–10.7]). PFS was superior in the TV versus chemotherapy arm (HR, 0.67 [95% CI, 0.54–0.82]; $P < .0001$). Confirmed ORR was 17.8% and 5.2% in the TV and chemotherapy arms, respectively (odds ratio, 4.0; 95% CI, 2.1–7.6; $P < .0001$). The NCCN Guidelines for Cervical Cancer recommend tisotumab vedotin-tftv as a preferred therapy option for the treatment of recurrent/metastatic cervical cancer with disease progression on or after chemotherapy regardless of biomarker status.

Cemiplimab as a Preferred, Second-line/Subsequent Therapy

Cemiplimab is a PD-1–blocking monoclonal activity shown to have anti-tumor activity against cervical cancer. The phase 3, randomized, Empower-Cervical-1 clinical trial evaluated the efficacy of cemiplimab or investigator’s choice of chemotherapy (topotecan, vinorelbine, gemcitabine, irinotecan, or pemetrexed) in patients with recurrent or metastatic cervical cancer who have progressed on prior therapy.³¹⁹ The trial enrolled 608 patients, who had previously received one or more lines of systemic therapy for recurrence, were randomized to either receive cemiplimab or chemotherapy. The median OS and PFS were significantly longer in the cemiplimab arm than in the control arm (12 vs. 8.5 months; HR, 0.69; 95% CI, 0.56–0.84; $P < .001$ and 2.8 vs. 2.9 months; HR, 0.75; 95% CI, 0.63–0.89; $P < .001$, respectively). 16% of the patients in the test arm achieved an OR (95% CI, 12.5–21.1) as compared to 6.3% (95% CI, 3.8–9.6) in the chemotherapy arm. The median OS in SCC and AC/ASC cervical cancer in cemiplimab versus chemotherapy arm was 11.1 versus 8.8 months (HR, 0.73; 95% CI, 0.58–0.91) and 13.3 versus 7 months (HR, 0.56; 95% CI, 0.36–0.85), respectively, indicating that there is an OS

benefit irrespective of histology. In a sub-analysis of the study, samples from 254 patients were evaluated for PD-L1 expression to test the efficacy of cemiplimab in tumors with PD-L1 expression of 1% or greater. The median OS of cemiplimab-treated PD-L1–expressed tumors (**CPS ≥ 1**) versus chemotherapy was 13.9 versus 9.3 months (HR, 0.70; 95% CI, 0.46–1.05) while the OS benefit for tumors with low PD-L1 expression (CPS < 1) was comparable in the two arms, although the authors of the study noted that due to smaller size of the sub-group population, reliable assessment of the benefits could not be made. In the interim OS analysis of this study presented at the 20233 European Society for Medical (ESMO) Conference, cemiplimab efficacy in PD-L1–positive (**CPS ≥ 1**) was further tested by evaluating samples from 371 patients. Median OS in PD-L1–positive (**CPS ≥ 1**) tumors for cemiplimab versus chemotherapy was 12.1 versus 7.7 months (HR, 0.61, 0.45–0.83), respectively, whereas in tumors with PD-L1 CPS < 1 , OS was 10.8 versus 7 months (HR, 0.65, 0.43–0.98), respectively, indicating that the cemiplimab has continued to show meaningful clinical benefits in both populations.³²⁰ According to the patient reported outcomes reported.³²¹ Cemiplimab conferred favorable differences in global health status (GHS)/quality of life (QoL) and physical functioning (PF) compared with chemotherapy among patients with recurrent cervical cancer, and clinically meaningful differences favoring cemiplimab in role functioning, appetite loss, and pain. In version 1.2024 of the NCCN Guidelines for Cervical Cancer, cemiplimab was added as a preferred, second line/subsequent-therapy option.

Chemotherapy as Other Recommended, Second-line/Subsequent Therapy

The Panel re-evaluated the list of single-agent chemotherapies included as second-line/subsequent therapy options under the other recommended regimens category by re-voting on each of these agents for their efficacy and use based on Panel members’ clinical experience and judgement. The Panel agreed to include the following options as second-line/subsequent treatment: bevacizumab, paclitaxel,

albumin-bound paclitaxel, docetaxel, fluorouracil, gemcitabine, pemetrexed, topotecan, vinorelbine, and irinotecan.

Biomarker-Directed, Useful in Certain Circumstances, Second-line/Subsequent Therapy

The NCCN Guidelines for Cervical Cancer have included a list of biomarkers with their associated targeted treatments as second-line/subsequent therapies under “useful in certain circumstances” options. The *Pathology* section of the Guidelines provides recommendations for individual biomarkers that should be evaluated for targeted therapy.

Nivolumab for PD-L1–Positive Tumor

Nivolumab, a checkpoint inhibitor, has shown efficacy in patients with recurrent/metastatic cervical cancer who received at least one prior chemotherapy regimen. Based on Checkmate-358 data (see *Prognostic and Predictive Biomarkers* section), in the 1.2023 version of the NCCN Guidelines for Cervical Cancer, the Panel moved nivolumab from preferred, second-line or subsequent therapy options to the “useful in certain circumstances” category for PD-L1–positive tumors and continues to recommend nivolumab in the same category in version 2.2024.

Trastuzumab Deruxtecan for HER2-Positive Tumor

Another tumor-agnostic study evaluated the durability and clinically meaningful response of trastuzumab deruxtecan across multiple HER2-expressing (IHC 3+ or 2+) advanced solid tumor types in patients who progressed on prior therapy or who have no satisfactory alternative treatment options. HER2 expression is observed in a wide range of solid tumors and is an established prognostic biomarker for breast, gastric, and colorectal cancers. Cervical cancer has shown HER2 positivity rate of approximately 2% to 6% in the literature.¹⁵⁶⁻¹⁵⁸ Trastuzumab deruxtecan is an antibody-drug conjugate that contains the humanized anti-HER2

monoclonal antibody trastuzumab attached to the topoisomerase inhibitor deruxtecan.¹⁵⁹

Based on DESTINY-PanTumor02 (see *Prognostic and Predictive Biomarkers* section) Version 2.2024 of the NCCN Guidelines for Cervical Cancer includes fam-trastuzumab deruxtecan-nxki as a category 2A, useful in certain circumstances, second line/subsequent therapy option for HER2-positive tumors (IHC 3+ or 2+). The Panel recommends HER2 IHC testing (with reflex to HER2 FISH for equivocal IHC) for advanced, metastatic or recurrent cervical carcinoma.

Selpercatinib for RET-Gene Fusion Tumor

Selpercatinib received tumor-agnostic approval by the FDA for patients with solid tumors with a *RET* gene fusion that has progressed on or following prior systemic treatment or who have no satisfactory alternative treatment options. The NCCN Panel recommends selpercatinib as a biomarker-directed second-line/subsequent therapy under useful in certain circumstances category for *RET*- gene fusion-positive tumors given its efficacy in tumor-agnostic population. The NCCN Panel also specified that *RET* gene fusion testing may be considered for patients with locally advanced or metastatic cervical cancer (see *Prognostic and Predictive Biomarkers* section).

TRK Inhibitors for NTRK-Gene Fusion Tumor

In addition to selpercatinib, other targeted therapy regimens included in the NCCN Guidelines for Cervical Cancer as biomarker-directed second-line/subsequent therapies that have been approved in a tumor-agnostic population are the tropomyosin receptor kinase (TRK) inhibitors, larotrectinib and entrectinib. Larotrectinib targets the TRK proteins that are encoded by the genes *NTRK1*, *NTRK2*, and *NTRK3*. *NTRK* gene fusions are found in about 1% of all solid tumors. The NCCN Guidelines for Cervical Cancer recommend larotrectinib and entrectinib as a second-line or subsequent, useful in certain circumstances option for

NTRK-gene fusion positive tumors and have changed the category of evidence from category 2B to category 2A based on FDA approval and several clinical trials (see *Prognostic and Predictive Biomarkers* section).

Pembrolizumab has been added as a preferred regimen for second-line option for treating PD-L1–positive or MSI-H/dMMR cervical tumors (category 2A).^{144,311,322} Other recommended agents (all category 2B) that have shown responses or prolongation of PFS and may be useful as second-line therapy include bevacizumab,³²³ albumin-bound paclitaxel (ie, nab-paclitaxel),³²⁴ docetaxel,³²⁵ fluorouracil,³²⁶ gemcitabine,³²⁷ ifosfamide,^{328,329} irinotecan,³³⁰ mitomycin,³³¹ pemetrexed,³³² topotecan,^{333,334} and vinorelbine.³³⁵

Other Agents

Targeted therapies and biologics have an established role for selected cases of cervical cancer. Pembrolizumab and bevacizumab have been included in the Guidelines for treating recurrent or metastatic disease. The use of these and other targeted or biologic agents remains an active area of investigation.

Principles of Radiation Therapy

Radiation therapy is often used in the management of patients with cervical cancer either 1) as definitive therapy for those with locally advanced disease or for those who are poor surgical candidates; or 2) as adjuvant therapy following radical hysterectomy for those who have one or more pathologic risk factors (eg, positive lymph nodes, parametrial infiltration, positive surgical margins, large tumor size, deep stromal invasion, LVSI).

The algorithm provides general RT dosage recommendations, which should not be interpreted as stand-alone recommendations because RT techniques and clinical judgment are an essential part of developing an appropriate treatment regimen. The ASTRO clinical practice guideline on

radiation therapy for cervical cancer provides recommendations for the use of radiation therapy in the treatment of nonmetastatic cervical cancer, including postoperative radiation therapy for intermediate and high-risk factors, chemoradiation for stages IB3–IVA, and RT or chemoradiation for stages IA1–IB2 if medically inoperable. The guideline emphasizes the importance of intensity modulated radiation therapy (IMRT) and brachytherapy, as well as the use of image-guided adaptive brachytherapy and MRI for treatment planning.³³⁶

Optimum staging of disease to precisely delineate the primary tumor volume and draining lymph nodes, including abdominopelvic radiologic studies (CT, MRI, or combined PET/CT scans), is recommended in patients with stage IB2, IIA2, or advanced-stage tumors. Contemporary imaging studies must be correlated with careful assessment of clinical findings to define tumor extent, especially regarding vaginal or parametrial extension.

Radiation Treatment Planning

Technologic advances in imaging, computer treatment planning systems, and linear accelerator technology have enabled the more precise delivery of radiation doses to the pelvis. However, physical accuracy of dose delivery must be matched to a clear understanding of tumor extent, potential pathways of spread, and historical patterns of locoregional recurrence to avoid geographic misses.

CT-based treatment planning with conformal blocking and dosimetry is considered standard care for EBRT. In patients who are not surgically staged, FDG-PET imaging is useful to help define the nodal volume of coverage and may be useful postoperatively to confirm removal of abnormal nodes.³³⁷ IMRT technique is preferred to minimize toxicities in definitive treatment of the pelvis with or without para-aortic treatment. Regular use of image-guided radiation therapy (IGRT) with orthogonal

imaging and/or routine volumetric imaging (such as cone beam CT) at the time of treatment delivery, is essential to ensure appropriate coverage of targets and sparing of normal tissues. Brachytherapy is a critical component of definitive therapy in patients with cervical cancer who are not candidates for surgery (ie, those with an intact cervix); it may also be used as adjuvant therapy. Brachytherapy is typically combined with EBRT in an integrated treatment plan. MRI imaging immediately preceding brachytherapy may be helpful in delineating residual tumor geometry. Stereotactic body radiotherapy (SBRT) allows delivery of very high doses of focused external beam radiation and may be applied to isolated metastatic sites.^{62,338}

Routine image guidance, such as cone-beam CT (CBCT), may be helpful in defining daily internal soft tissue positioning. Concepts regarding the gross target volume (GTV), clinical target volume (CTV), planning target volume (PTV), organs at risk (OARs) and dose-volume histogram (DVH) have been defined for use in conformal radiotherapy, especially for IMRT.³³⁹⁻³⁴¹

Point A, representing a paracervical reference point, has been the most widely used, validated, and reproducible dosing parameter used to date. However, limitations of the Point A dosing system include the fact that it does not consider the three-dimensional shape of tumors, nor individual tumor to normal tissue structure correlations.

Traditionally point A doses were based on widely validated dose fractionation for brachytherapy with low dose rate (LDR). The dose at point A assumes an LDR delivery of 40–70 cGy/h. The traditional LDR point A prescription dose was 70–80 Gy. Typical point A prescription doses are 5.5 Gy X 5 fractions for early disease and 6 Gy X 5 fractions for large tumors or those demonstrating a poor response. Another reasonable choice that has been well-studied in European trials for intracavity dosing to the high-risk CTV (HR-CTV) is 28 Gy in 4 fractions.³⁴²

Ferrigno et al published a report on the comparative outcome of cervical cancer patients treated with LDR and high dose rate (HDR) brachytherapy.³⁴³ In this retrospective analysis, 190 patients were treated with LDR brachytherapy and 118 patients were treated with HDR brachytherapy. 57.4% of patients in the LDR group were FIGO stage II, 36.3% with stage III and 6.3% with stage I disease. In the HDR group, 47.4% of patients were FIGO stage III, 43.2% with stage II and 9.3% with stage I disease. Median doses of LDR brachytherapy at Point A were 40 Gy and 50 Gy for patients treated with 1 and 2 implants, respectively. All patients from the HDR group were treated with 24 Gy in 4 fractions of 6 Gy to Point A.

With a median follow-up time of 70 months (LDR) and 33 months (HDR) groups, the OS, DFS, and local control at 5 years were better in the LDR group (69% vs. 55%, $P = .007$; 73% vs. 56%, $P = .002$; and 74% vs. 65%, $P = .04$, respectively) for all stages combined. However, for clinical stages I and II, no differences were seen in OS, DFS, and local control at 5 years between the two groups. For clinical stage III, although OS and DFS at 5 years were better in the LDR than in the HDR group (46% vs. 36%, $P = .04$ and 49% vs. 37%, $P = .03$, respectively), the 5-year probability of rectal complications was higher in the LDR group than in the HDR group (16% vs. 8%, $P = .03$).

Thus, similar outcomes were observed for patients who were stages I and II treated with either HDR or LDR brachytherapy. Although lower overall and disease-free survival and marginally lower local control were observed for patients who were stage III treated with HDR brachytherapy, less late rectal complications were observed in this group. These findings were probably the result of the relatively low HDR brachytherapy dose delivered at Point A.

There are increasing efforts to use and standardize image-based volumetric brachytherapy approaches using MR, CT or ultrasound –

international validation efforts with different studies including EMBRACE-I study, which is a benchmark study that represents a positive breakthrough in the treatment of locally advanced cervical cancer.^{342,344-349}

One such study analyzed the details of brachytherapy practice in cervical cancer patients in the United States between 1996 and 1999 to understand the impact of different practices across different facilities.³⁵⁰ A total of 442 patient records were reviewed in 59 different radiation facilities that were selected from a stratified random sample to obtain data about patients' characteristics including tumor extent, and treatment. Unless otherwise specified, brachytherapy practice was based on the 408 patients who had their brachytherapy or all their treatment at the surveyed facility. A total of 91.5% of patients underwent brachytherapy at the initial treating institution; 8.5% were referred to a second site for brachytherapy. Of these patients who had brachytherapy, 77.8%, 13.3%, and 0.9%, respectively, were treated with LDR, HDR, or a combination of HDR and LDR brachytherapy; 7.9% had interstitial brachytherapy (5.7% LDR and 1.9% HDR, 0.3% mixed). The median duration of treatment and median Point A dose were very similar for patients treated with HDR or LDR. Patients with HDR were treated using a variety of treatment schedules. Different applicator types were favored for LDR versus HDR. Of patients treated with HDR, 73.4% had no brachytherapy bladder or rectal doses recorded, suggesting that full dosimetric calculations were performed only for the first fraction in many institutions. Facility size significantly impacted on referral to another institution for brachytherapy, brachytherapy dose, and treatment duration.

In EMBRACE-I trial, a prospective, observational, multicenter cohort study, cervical cancer patient data from 24 centers in Europe, Asia, and North America with FIGO stage 1B–IVA or stage IVB restricted to para-aortic lymph metastasis below the L1–L2 interspace were prospectively collected.³⁴⁴ The patients were treated with CRT followed by MRI-based image-guided adaptive brachytherapy (IGABT) with primary endpoints

being local control and late morbidity. Among 1341 patients analyzed, the actuarial overall 5-year local control was 92% (95% CI, 90–93) at a median follow-up of 51 months and actuarial cumulative 5-year incidence of grade 3–5 morbidity from 1251 patients was 6.8% (95% CI, 5.4–8.6) for genitourinary events, 8.5% (6.9–10.6) for gastrointestinal events, 5.7% (4.3–7.6) for vaginal events, and 3.2% (2.2–4.5) for fistulae. CRT and MRI-based IGABT result in effective and stable long-term local control across all stages of locally advanced cervical cancer, with a limited severe morbidity per organ.

A unified approach to techniques and prescription/fractionation schedules for both EBRT and IGABT is required and RetroEMBRACE and EMBRACE I studies have demonstrated that clinical outcome is related to dose prescription and technique. The EMBRACE II study is an interventional and observational multicenter study which aims to benchmark a high level of local, nodal, and systemic control while limiting morbidity, using an advanced target volume selection and contouring protocol for EBRT and a multi-parametric brachytherapy dose prescription protocol for brachytherapy, and use of advanced EBRT (IMRT and IGRT) and brachytherapy (Intracavitary/Interstitial-IC/IS) techniques.³⁵¹

For EMBRACE-II, 153 patients were treated with: IMRT/VMAT, daily IGRT, 45 Gy over 25 fractions for the elective CTV, and simultaneously integrated boost for pathologic lymph nodes. Application of IMRT/VMAT, IGRT, and a 45 to Gy dose provides the potential of higher conformality inducing significant reduction of treated volume and the study is currently underway.³⁵² For patients with locally advanced cancers, initial radiation treatment of 40 to 45 Gy to the whole pelvis is often necessary to obtain tumor shrinkage to permit optimal intracavitary placements. With low dose-rate intracavitary systems, total doses from brachytherapy and EBRT to point A of at least 80 Gy are currently recommended for small tumors, with doses of 85 Gy or higher recommended for larger tumors

(http://www.americanbrachytherapy.org/guidelines/cervical_cancer_taskgroup.pdf).¹⁶⁴

For lesions in the lower one third of the vagina, the inguinal lymph nodes must be treated. The use of extended-field radiation to treat occult or macroscopic para-aortic lymph node disease must be carefully planned to ensure an adequate dose (45 Gy for microscopic disease) without exceeding bowel, spinal cord, or renal tolerances.³⁵³ General recommendations for radiation volumes and doses are discussed in the algorithm.

Intensity-modulated RT is becoming more widely available; however, issues regarding target definition, patient and target immobilization, tissue deformation, toxicity, and reproducibility remain to be validated.³⁵⁴⁻³⁶¹ Initial phase II hematologic toxicity data from RTOG 418 suggested that limiting the volume of bone marrow treated with IMRT was an important consideration for patients with cervical cancer who were receiving concurrent chemotherapy.³⁶² The reported TIME-C trial (RTOG 1203, NCT01672892) compared post-hysterectomy patients receiving adjuvant IMRT or standard four-field RT to determine whether IMRT reduced acute toxicity. Among the 278 patients with cervical and endometrial cancer included in the analysis, pelvic IMRT was associated with significantly lower scores for gastrointestinal and urinary toxicity than standard RT.³⁶³ Dose-escalated IMRT (limiting V55 to below 15 cm³ and limiting the dose to duodenum) can safely and effectively treat para-aortic nodal disease in gynecologic malignancies reducing the risk of late duodenal toxicity.³⁶⁴ Among 105 patients with gynecologic primary tumors (including 38 cervical patients) and treated to a nodal clinical target volume to 45 to 50.4 Gy with a boost to 60 to 66 Gy, only nine of 105 patients (2/38 cervical patients) experienced duodenal toxicity with 3-year actuarial rate of any duodenal toxicity of 11.7%. IMRT technique can reduce acute and chronic gastrointestinal and hematologic toxicity. An International Multicenter

Phase II Clinical Trial (INTERTECC-2) evaluated acute hematologic and gastrointestinal (GI) toxicity for patients with locoregionally in which 83 patients met the eligibility criteria and received weekly cisplatin concurrently with once-daily IMRT, followed by intracavitary brachytherapy.³⁶⁵ The primary endpoint was the occurrence of either acute grade ≥ 3 neutropenia or clinically significant GI toxicity within 30 days of completing chemoradiation therapy. The incidence of any primary event was 26.5% (95% CI, 18.2%–36.9%), and the incidence of grade ≥ 3 neutropenia and clinically significant GI toxicity was 19.3% (95% CI, 12.2%–29.0%) and 12.0% (95% CI, 6.7%–20.8%), respectively. Compared with patients treated without IG-IMRT (n = 48), those treated with IG-IMRT (n = 35) had a significantly lower incidence of grade ≥ 3 neutropenia (8.6% vs. 27.1%; 2-sided χ^2 ; $P = .035$). Several retrospective analyses suggest that prolonged RT treatment duration has an adverse effect on outcome.³⁶⁶⁻³⁷⁰ Extending the overall treatment beyond 6 to 8 weeks can result in approximately a 0.5% to 1% decrease in pelvic control and cause specific survival for each extra day of overall treatment time. Thus, although no prospective randomized trials have been performed, it is generally accepted that the entire RT course (including both EBRT and brachytherapy components) should be completed in a timely fashion (within 8 weeks); delays or splits in the radiation treatment should be avoided whenever possible.

Techniques for re-irradiation may include IORT, intracavitary or interstitial brachytherapy, SBRT, IMRT, or proton therapy.³⁷¹⁻³⁷³ Such cases are highly customized and depend on the target, proximity to critical organs, previous RT dose, extent of overlap, and time intervals since prior RT. The appropriate dose for each case needs to be individualized.

Normal Tissue Considerations

Planning for RT in cervical cancer must take into account the potential impact on surrounding critical structures, such as rectum, bladder,

sigmoid, small bowel, and bone. Acute effects (i.e., diarrhea, bladder irritation, fatigue) occur to some degree in most patients undergoing radiation and are typically magnified by concurrent chemotherapy. However, acute effects can often be managed with medications and supportive care, and they generally resolve soon after completion of radiation. To avoid treatment-related menopause, ovarian transposition can be considered before pelvic RT in select young patients (<45 years with early-stage disease).¹⁶⁹⁻¹⁷¹

After therapy for cervical cancer, late side effects may include potential injury to bladder, rectum, bowel, and pelvic skeletal structures.³⁷⁴ The risk of major complications (eg, obstruction, fibrosis/necrosis, and fistula) is related to the volume, total dose, dose per fraction, and specific intrinsic radiosensitivity of the normal tissue that is irradiated.^{353,375,376} Careful blocking in order to minimize normal tissue exposure while maintaining tumor coverage is critical for optimal outcomes. In addition, patient-related conditions (ie, inflammatory bowel disease, collagen-vascular disease, multiple abdominal/pelvic surgeries, history of pelvic inflammatory disease, diabetes) influence determination of radiation dose and volumes.

For most patients, it is generally accepted that the whole pelvis can tolerate an external-beam radiation dose of 40 to 50 Gy. Gross disease in the parametria or unresected nodes may be treated with tightly contoured external-beam boosts to 60 to 65 Gy. Intracavitary brachytherapy boosts require attention to proper placement of the applicators within the uterus and against the cervix and vaginal apex, as well as appropriate packing to maximally displace the bladder and rectum. SBRT is not considered an appropriate routine alternative to brachytherapy. Normal tissue dose constraint guidelines for cervical cancer are added to the guidelines. Although the suggested dose constraints are provided in the guidelines, the NCCN Panel recommends that the clinicians must balance the risks of normal tissue toxicity with tumor control.

Incidental Cervical Cancer

Invasive cervical carcinoma is sometimes found incidentally after extrafascial hysterectomy. Workup for these patients includes history and physical examination, CBC (including platelets), and liver and renal function tests. Recommended radiologic imaging includes chest radiography, CT, or combined PET/CT; MRI may be performed if indicated to rule out gross residual disease. However, imaging is optional for patients with stage IB1 or smaller tumors.

No definitive data is available to guide the appropriate adjuvant treatment of these patients. Surveillance is recommended for patients with stage IA1 cervical cancer who do not have LVSI. For patients with either stage IA1 with LVSI, stage IA2/IB disease, or positive margins/gross residual disease, the Panel believes that a reasonable treatment schema should be based on the status of the surgical margins. If margins are positive and imaging is negative for nodal disease, then pelvic RT with concurrent platinum-containing chemotherapy with (or without) individualized brachytherapy is recommended. Recommended radiosensitizing regimens include cisplatin (preferred), carboplatin (preferred if patient is cisplatin-intolerant), or cisplatin/fluorouracil.

If margins or imaging is negative in stage IA2 or greater tumors, options include: 1) pelvic RT with brachytherapy, with (or without) concurrent platinum-containing chemotherapy; or 2) if Sedlis Criteria are not met on the hysterectomy specimen, consideration of complete parametrectomy, upper vaginectomy, and pelvic lymphadenectomy with (or without) para-aortic lymph node sampling (category 2B for para-aortic lymph node sampling). Typically, observation is recommended for patients with negative lymph nodes and no residual disease. However, chemoradiation with (or without) vaginal brachytherapy is recommended for subsequent findings of positive nodes, surgical margins, and/or parametrium.

For hysterectomy specimens with positive margins, gross residual disease, positive imaging, or primary tumor characteristics meeting Sedlis Criteria, pelvic EBRT with concurrent platinum-containing chemotherapy (with individualized brachytherapy for positive vaginal margins) is recommended.¹³⁵

Small Cell Neuroendocrine Carcinoma of the Cervix

Overview

Neuroendocrine tumors (NETs) are a highly heterogeneous group of neoplasms derived from ubiquitous neuroendocrine cells, mostly from the lungs, the gastrointestinal tract, and the pancreas, but more rarely are found in almost all body tissues including uncommon sites, such as female genital tract.³⁷⁷ The 2014 WHO Classification of neuroendocrine tumors has been updated with adoption of the terms low-grade NET and high-grade neuroendocrine carcinoma (NEC). In the endometrium and cervix, high-grade neuroendocrine neoplasms (NEC) are much more prevalent than low-grade and are more common in the cervix.³⁷⁸

NECC accounts for about 1% to 1.5% of all cervical cancers and is an aggressive histological variant of cervical cancer.³⁷⁹ Although rare, the cervix is the most common site for neuroendocrine carcinoma (eg, small cell and large cell neuroendocrine carcinoma) in the genital tract. Small cell NEC is the most common type of NECC, whereas well-differentiated NET, especially NET G1 (typical carcinoid) and NET G2 (atypical carcinoid), are very rare at this location.³⁷⁸

Primary Workup

Small cell neuroendocrine cervical cancer is an aggressive type of cervical cancer and most data on treatment regimens for this disease have been adapted from NCCN lung and pulmonary disease-management guidelines

(https://www.nccn.org/professionals/physician_gls/pdf/neuroendocrine.pdf) and (https://www.nccn.org/professionals/physician_gls/pdf/nscl.pdf)

given that small cell disease is commonplace in those settings. Because this condition is rare in the gynecologic realm and few data are available on small cell cervical cancer, high-level randomized trials are difficult to achieve and some of the primary workup and treatment recommendations are based on cervical cancer guidelines as well.³⁸⁰ FIGO staging system is implemented to describe characteristics and outcomes of patients with small cell neuroendocrine carcinoma of the cervix (small cell NECC) since it is more predictive than the two-tier staging system. Most patients were treated with cisplatin and etoposide.³⁸¹

Radical hysterectomy with pelvic lymphadenectomy with or without para-aortic lymph node sampling is one of the primary treatment options recommended for NECC tumors confined to the cervix (≤ 4 cm), followed by adjuvant treatment with chemotherapy (cisplatin/etoposide or carboplatin/etoposide) or chemoradiation. Chemoradiation and brachytherapy combination is also a recommended primary treatment with additional consideration of systemic therapy. For NECC tumors confined to the cervix that are greater than 4 cm, chemoradiation along with brachytherapy or neoadjuvant chemotherapy with cisplatin/etoposide or carboplatin/etoposide is also a primary treatment option. Radical hysterectomy can be considered if not previously done, followed by adjuvant radiation or chemoradiation.

Metastatic disease workup is the same as stage IVB or recurrent cervical cancer with distant metastasis (see *Therapy for Metastatic Disease*). For the locally advanced disease (stage IB3–IVA), the preferred primary treatment option is chemoradiation with brachytherapy with or without the addition of chemotherapy. Other treatment options include neoadjuvant chemotherapy followed by chemoradiation and brachytherapy. Based on the treatment response and disease persistence or recurrence, the patient can be further treated with other systemic therapy/best supportive care/pelvic exenteration.

Principles of Pathology

NECC is clinically aggressive, with rapid metastasis and a frequently poor clinical outcome. NECC is usually HPV-associated; types 16 and 18 are the most common (18 more often than 16).³⁸² This carcinoma type morphologically resembles neuroendocrine carcinomas of the lung. Small cell NECC is a morphologic diagnosis regardless of IHC staining profile. Most NECCs are diffusely positive for p16 due to the presence of high-risk HPV. However, p16 positivity cannot be used to aid in determining the site of origin; neuroendocrine carcinomas arising at other sites may strongly express p16 due to a non-HPV-related process.

If the tumor demonstrates classic morphologic features of small cell NECC, the diagnosis can be made in the absence of IHC neuroendocrine positivity because of the high variability in the expression levels. Small cell NECC is variably positive for chromogranin, CD56, and synaptophysin by IHC. CD56 and synaptophysin are the most sensitive neuroendocrine markers, but CD56 lacks specificity. Chromogranin is the most specific neuroendocrine marker but lacks sensitivity with only about 50% to 60% of small cell NECC being positive. Insulinoma-associated protein 1 (INSM1) and synaptophysin are other neuroendocrine markers, with 80% and 70% positivity, respectively.^{383,384} A high percentage of primary NECCs are thyroid transcription factor-1 (TTF1)-positive, including some with diffuse immunoreactivity, and this marker is of no value in distinction from a pulmonary metastasis. Small cell NECC may be only focally positive (often punctuate cytoplasmic staining) or even negative with broad-spectrum cytokeratins.

Systemic Therapy

NECC, being a rare variant of cervical cancer with a poor prognosis, based on a systematic review, multimodality treatment with radical surgery and neoadjuvant/adjuvant chemotherapy with cisplatin and etoposide with or without radiotherapy is the mainstay of treatment for early-stage disease while chemotherapy with cisplatin and etoposide or topotecan,

paclitaxel, and bevacizumab is appropriate for women with locally advanced or recurrent NECC.³⁷⁹

The dosing and schedule for chemoradiation and first-line adjuvant therapy are based on [NCCN Guidelines for Small Cell Lung Cancer](#) (SCL-E). Cisplatin and etoposide combination is one of the most common adjuvant chemotherapy regimens based on literature and tend to have a better prognosis.³⁸⁵ and is the preferred regimen in chemoradiation and first-line therapy for recurrent or metastatic small cell NECC.

Many physicians use carboplatin/paclitaxel because of ease of administration and tolerability, similar to cervical cancer.^{293,294} The addition of atezolizumab to chemotherapy in the first-line treatment of extensive-stage small-cell lung cancer resulted in significantly longer overall survival and progression-free survival than chemotherapy alone.³⁸⁶ A double-blind, placebo-controlled, phase 3 trial evaluated atezolizumab plus carboplatin and etoposide in patients with extensive-stage small-cell lung cancer who had not previously received treatment. A total of 201 patients were randomly assigned to receive carboplatin and etoposide with atezolizumab and 202 patients were assigned to receive placebo after carboplatin and etoposide in the induction phase. At a median follow-up of 13.9 months, the median overall survival was 12.3 months in the atezolizumab group and 10.3 months in the placebo group (HR for death, 0.70; 95% CI, 0.54–0.91; $P = .007$). The median PFS was 5.2 months and 4.3 months, respectively (HR for disease progression or death, 0.77; 95% CI, 0.62–0.96; $P = .02$). Based on these results in small cell lung cancer, a high-grade neuroendocrine carcinoma, the NCCN Panel recommends Cisplatin(or carboplatin)/etoposide with atezolizumab under other recommended regimens for recurrent or metastatic small cell NECC.

The CASPIAN trial³⁸⁷ assessed durvalumab, with or without tremelimumab, in combination with etoposide plus either cisplatin or carboplatin (platinum-etoposide) in patients with extensive-stage small cell

lung cancer (ES-SCLC) who never received treatment and demonstrated that first-line durvalumab plus platinum-etoposide significantly improved overall survival in patients with ES-SCLC. In this randomized, open-label, phase 3 trial, 268 patients were randomly allocated to the durvalumab plus platinum-etoposide group and 269 to the platinum-etoposide group. Durvalumab plus platinum-etoposide was associated with a significant improvement in overall survival, with HR of 0.73 (95% CI, 0.59–0.91; $P = .0047$); median overall survival was 13.0 months (95% CI, 11.5–14.8) in the durvalumab plus platinum-etoposide group versus 10.3 months (9.3–11.2) in the platinum-etoposide group. Based on this trial data, a combination of durvalumab with Cisplatin (or carboplatin) and etoposide is one of the recommended regimens for first-line, recurrent or metastatic small cell NECC along with atezolizumab. Other recommended regimens for first line therapy for recurrent or metastatic small cell NECC includes topotecan, paclitaxel and bevacizumab combination. Frumovitz et al,³⁸⁸ assessed the activity of topotecan, paclitaxel, and bevacizumab (TPB) in recurrent small cell cervical cancer (SCCC) and compared the survival of patients with SCCC who received TPB versus not receiving this regimen. In this retrospectively analyzed study of women with recurrent SCCC who received chemotherapy as primary therapy, 13 women treated with TPB for first recurrence were compared to 21 women treated with non-TPB chemotherapy, most commonly platinum with or without a taxane. Median PFS was 7.8 months for TPB and 4.0 months for non-TPB regimens (HR, 0.21; 95% CI, 0.09–0.54; $P = .001$). Median OS was 9.7 months for TPB and 9.4 months for non-TPB regimens (HR, 0.53; 95% CI, 0.23–1.22; $P = .13$). These findings from the study indicated that TPB for recurrent SCCC significantly improved PFS over non-TPB regimens.

Cervical Cancer and Pregnancy

Cervical cancer is the most frequently diagnosed gynecologic malignancy in pregnant individuals; however, most of these patients have stage I disease.³⁸⁹⁻³⁹² Invasive cervical cancer during pregnancy creates a clinical

dilemma and requires multidisciplinary care.^{389,393} Patients must make the difficult decision either to delay treatment until documented fetal maturity or to undergo immediate treatment based on their stage of disease.^{390,393} Patients who delay treatment until fetal maturity should have their children delivered by cesarean section.^{392,394,395} Radical trachelectomy with preservation of pregnancy has been successfully performed in a few pregnant patients with early-stage cervical cancer.^{59,396-398} Patients with early-stage disease may prefer to have radical hysterectomy and node dissection instead of RT to avoid radiation fibrosis and to preserve their ovaries. Patients with stage I disease who delay treatment until fetal maturity can undergo cesarean section with concurrent radical hysterectomy and pelvic node dissection. For those choosing RT, traditional RT with (or without) chemotherapy protocols (described previously) may need to be modified.³⁹²

Drug Reactions

Virtually all drugs have the potential to cause adverse reactions, either during or after infusion.³⁹⁹ In cervical cancer treatment, drugs that more commonly cause adverse reactions include carboplatin, cisplatin, docetaxel, liposomal doxorubicin, and paclitaxel. Most of these drug reactions are mild infusion reactions (ie, skin reactions, cardiovascular reactions, respiratory or throat tightness), but more severe allergic reactions (ie, life-threatening anaphylaxis) can occur.^{400,401} In addition, patients can have severe infusion reactions and mild allergic reactions. Infusion reactions are more common with paclitaxel.⁴⁰² Allergic reactions (ie, true drug allergies) are more common with platinum agents (eg, cisplatin).^{402,403} Management of drug reactions is discussed in the [NCCN Guidelines for Ovarian Cancer](#).⁴⁰² Importantly, patients who experienced severe life-threatening reactions should not receive the implicated agent again unless evaluated by an allergist or specialist in drug desensitization. If a mild allergic reaction previously occurred and it is appropriate to re-administer the drug, a desensitization regimen is recommended even if

the symptoms have resolved. Various desensitization regimens have been published and should be followed.⁴⁰³⁻⁴⁰⁵ Patients must be desensitized with each infusion if they have had a previous reaction. Almost all patients can be desensitized.³⁹⁹ To maximize safety, patients should be desensitized in the intensive care unit.³⁹⁹

Gynecologic Survivorship

Treatment for gynecologic cancer typically involves surgery, chemotherapy, hormone therapy, RT, and/or immunotherapy, which may cause acute, short term, and long-term toxicities. Surgical approaches may be extensive and cause adhesions to form, which in turn may cause pain and contribute to the development of small bowel obstruction, urinary or gastrointestinal complications (eg, incontinence, diarrhea), pelvic floor dysfunction (manifested by a variety of urinary, bowel, and/or sexual effects), and lymphedema. Chemotherapy agents vary, though commonly used regimens may pose a significant risk of neurotoxicity, cardiac toxicity, cognitive dysfunction, and the development of hematologic cancers. Long term estrogen deprivation may cause symptoms such as hot flashes, vaginal dryness, and bone loss. RT may cause long-term complications (eg, fibrosis, stenosis, vulvovaginal atrophy) and may predispose patients to subsequent cancers of the skin, subcutaneous tissue, and/or underlying organs that are proximal to the radiation field. Use of immunotherapy agents in gynecologic cancers is emerging, and to date, long term effects of these treatments are unknown.

Following completion of treatment, all gynecologic cancer survivors should receive regular general medical care that focuses on managing chronic diseases (eg, depression, diabetes, hypertension), monitoring cardiovascular risk factors, receiving recommended vaccinations, and encouraging adoption of a healthy lifestyle (eg, promoting exercise, smoking cessation). To assess the late and long term effects of gynecologic cancers, clinicians should comprehensively document the

patient's history, including prior treatment history, and conduct a thorough physical examination followed by necessary imaging and/or laboratory testing. As most treatments for gynecologic cancers will cause sexual dysfunction, early menopause, and infertility, special attention to the resultant medical and psychosocial implications is needed. All patients, whether sexually active or not, should be asked about genitourinary symptoms, including vulvovaginal dryness. Post-radiation use of vaginal dilators and moisturizers is recommended. Psychosocial effects may include psychological (eg, depression, anxiety, fear of recurrence, altered body image), financial (eg, return to work, insurance concerns), and interpersonal (eg, relationships, sexuality, intimacy). Patients should be referred to appropriate specialty providers (eg, physical therapy, pelvic floor therapy, sexual therapy, psychotherapy) as needed, based on prior treatment history and assessed risk of developing late effects and/or existing concerns. Communication and coordination with all clinicians involved in the care of survivors, including primary care clinicians, is critical. Providing survivors with a summary of their treatment and recommendations for follow up is also recommended. To this end, the SGO has developed templates for gynecologic cancer specific survivorship care plans to aid survivors and their clinicians in summarizing cancer history, treatments received, possible side effects, and recommended follow up.

Best Supportive Care

Patients with refractory systemic cancer warrant a comprehensive coordinated approach involving hospice care, pain consultants, and emotional and spiritual support, individualized to the situation (see the [NCCN Guidelines for Palliative Care](#)).

Summary

Cervical cancer is decreasing in the United States because of the wide use of screening; however, it is increasing in developing countries

National
Comprehensive
Cancer
Network®

NCCN Guidelines Version 3.2024

Cervical Cancer

(~275,000 deaths/year), because screening is not available to many. Effective treatment for cervical cancer (including surgery and concurrent chemoradiation) can yield cures in 80% of patients with early-stage disease (stages I–II) and in 60% of patients with stage III disease. The hope is that immunization against HPV (using vaccines) will prevent persistent infection with the types of HPV against which the vaccine is designed and will therefore prevent specific HPV cancer.^{26,27,406}
